- Lawrence Kohlberg proposed a stage theory of moral reasoning, from a preconventional morality of self-interest, to a conventional morality concerned with upholding laws and social rules, to (in some people) a postconventional morality of universal ethical principles.
- Other researchers believe that morality lies in moral intuition and moral action as well as thinking.
- Some critics argue that Kohlberg's postconventional level represents morality from the perspective of individualist cultures.

Multiple-Choice Questions

1. Walter Mischel's famous "marshmallow test" found that

a. adolescents are unable to control most impulses.

b. adults who can delay gratification often have lower paying jobs.
c. children who can delay gratification are often successful as adults.
d. children who can delay gratification often do not flourish as adults.
e. adolescents who can delay gratification tend to be at the preconventional level of morality.

2. ______ focused on moral intuition and how people feel about moral situations. _______, however, was more interested in moral reasoning and how people think about moral situations.

a. Kohlberg; Erikson
b. Erikson; Kohlberg
c. Piaget; Kohlberg
d. Piaget; Erikson
e. Haidt; Kohlberg

3. Howard cheats in his calculus class, even though he knows it is wrong, because “everyone else is doing it.” Kohlberg would argue that Howard’s response reflects a _______ view of morality.

a. myelinated
b. preconventional
c. conventional
d. postconventional
e. formal operational

4. What development in adolescents allows for greater impulse control?

a. The hormonal surge of early adolescence
b. Hindbrain changes associated with the onset of puberty
c. Frontal lobe maturation in late adolescence
d. Limbic system development in mid-adolescence
e. A decrease in myelin production throughout adolescence

5. Piaget would argue that as an adolescent, Mildred is better able to understand calculus because she is in the

a. sensorimotor stage.
b. preoperational stage.

c. concrete operational stage.
d. formal operational stage.
e. accommodation stage.

Practice FRQs

1. Even though they complain about how much they pay each year, the Singers dutifully pay their taxes. Provide an explanation Kohlberg might give for the reasoning behind the Singers' tax-paying behavior for each of his stages of moral thinking.

Answer

1 point: Preconventional morality: The Singers pay their taxes to avoid being punished with additional fines or jail time if they fail to pay. Pages 535–536

1 point: Conventional morality: The Singers pay their taxes simply because doing so is the rule. Pages 535–536

1 point: Postconventional morality: The Singers pay their taxes, even though they don't want to, because they feel it's the right thing to do to support government programs for people in need. Pages 535–536

2. Analyze how the following concepts might affect a middle school student who is asked by his friends to skip science class and hide in the bathroom at school.

- The timing of puberty
- The maturity of the teenage brain
- Conventional morality

(3 points)

Module **52 Adolescence: Social Development and Emerging Adulthood**

LEARNING TARGETS

- 52-1 Describe the social tasks and challenges of adolescence.
- 52-2 Contrast parental and peer influences during adolescence.
- 52-3 Discuss the characteristics of *emerging adulthood*.

52-1 What are the social tasks and challenges of adolescence?

Theorist Erik Erikson (1963) contended that each stage of life has its own *psychosocial* task, a crisis that needs resolution. Young children wrestle with issues of *trust*, then *autonomy* (independence), then *initiative*. School-age children strive for *competence*, feeling able and productive. But for people your age, the task is to synthesize past, present, and future possibilities into a clearer sense of self (**Table 52.1**). Adolescents wonder, “Who am I as an individual? What do I want to do with my life? What values should I live by? What do I believe in?” Erikson called this quest the adolescent’s *search for identity*.

TABLE 52.1 Erikson’s Stages of Psychosocial Development

Stage (approximate age)	Issue	Description of Task

Infancy (to 1 year)	Trust vs. mistrust	If needs are dependably met, infants develop a sense of basic trust.
Toddlerhood (1 to 3 years)	Autonomy vs. shame and doubt	Toddlers learn to exercise their will and do things for themselves, or they doubt their abilities.
Preschool (3 to 6 years)	Initiative vs. guilt	Preschoolers learn to initiate tasks and carry out plans, or they feel guilty about their efforts to be independent.
Elementary school (6 years to puberty)	Competence vs. inferiority	Children learn the pleasure of applying themselves to tasks, or they feel inferior.
Adolescence (teen years into 20s)	Identity vs. role confusion	Teenagers work at refining a sense of self by testing roles and then integrating them to form a single identity, or they become confused about who they are.
Young adulthood (20s to early 40s)	Intimacy vs. isolation	Young adults struggle to form close relationships and to gain the capacity for intimate love, or they feel socially isolated.
Middle adulthood (40s to 60s)	Generativity vs. stagnation	Middle-aged people discover a sense of contributing to the world, usually through family and work, or they may feel a lack of purpose.
Late adulthood (late 60s and up)	Integrity vs. despair	Reflecting on their lives, older adults may feel a sense of satisfaction or failure.

As sometimes happens in psychology, Erikson's interests were bred by his own life experience. As the son of a Jewish mother and a Danish Gentile father, Erikson was "doubly an outsider," reported Morton Hunt (1993, p. 391). He was "scorned as a Jew in school but mocked as a Gentile in the synagogue because of his blond hair and blue eyes." Such episodes fueled his interest in the adolescent struggle for identity.

AP® EXAM TIP

Become familiar with Table 52.1, Erikson’s Stages of Psychosocial Development, and be able to identify an individual that may be dealing with the issue in each stage. For example, a teenager may be dealing with the identity versus role confusion issue.

Forming an Identity

▶ Flip it Video: Adolescent Identity Development

To refine their sense of identity, adolescents in individualist cultures usually try out different "selves" in different situations. They may act out one self at home, another with friends, and still another at school or online. If two situations overlap—as when a teenager brings new friends home—the discomfort can be considerable (Klimstra et al., 2015). The teen often wonders, "Which self should I be? Which is the real me?" The eventual resolution is a self-definition that unifies the various selves into a consistent and comfortable sense of who one is—an **identity**.

identity

our sense of self; according to Erikson, the adolescent's task is to solidify a sense of self by testing and integrating various roles.

> “ *Somewhere between the ages of 10 and 13 (depending on how hormone-enhanced their beef was), children entered adolescence, a.k.a. 'the de-cutening'.* ”
>
> *Comedian Jon Stewart et al.,* Earth (The Book), *2010*

For both adolescents and adults, group identities are often formed by how we differ from those around us. When living in Britain, I [DM] become conscious of my Americanness. When spending time in Hong Kong, I [ND] become conscious of my minority White race. For international students, for those of a minority ethnic or religious group, for gay and transgender people, or for people with a disability, a **social identity** often forms around their distinctiveness.

social identity

the "we" aspect of our self-concept; the part of our answer to "Who am I?" that comes from our group memberships.

Erikson noticed that some adolescents forge their identity early, simply by adopting their parents' values and expectations. Other adolescents may adopt the identity of a particular peer group—jocks, preps, geeks, band kids, debaters. Traditional, collectivist cultures teach adolescents who they are, rather than encouraging them to decide on their own. Bicultural adolescents form complex identities as they integrate multiple group memberships and their feelings about them (Marks et al., 2011).

Most young people develop a sense of contentment with their lives. Which statement best describes you: "I would choose my life the way it is right now" or "I wish I were somebody else"? When American teens answered, 81 percent picked the first, and 19 percent the second (Lyons, 2004). Reflecting on their existence, 75 percent of American collegians say they "discuss religion/spirituality" with friends, "pray," and agree that "we are all spiritual beings" and "search for meaning/purpose in life" (Astin et al., 2004; Bryant & Astin, 2008). This would not surprise Stanford psychologist William Damon and his colleagues (2003), who have contended that a key task of adolescence is to achieve a purpose—a desire to accomplish something personally meaningful that makes a difference to the world beyond oneself.

Competence versus inferiority

Top: © Ron Chapple/Corbis; Bottom: © Oliver Rossi/Corbis

Intimacy versus isolation

Several studies indicate that self-esteem typically falls during the early to mid-teen years, and, for girls, depression scores often increase. But then self-image rebounds during the late teens and twenties, and previous gender differences in self-esteem become small (Zuckerman et al., 2016). Late adolescence is also a time when agreeableness and emotional stability scores increase (Klimstra et al., 2009).

Left: Tristan Savatier/Getty Images; Right: Juliana Wiklund/Getty Images

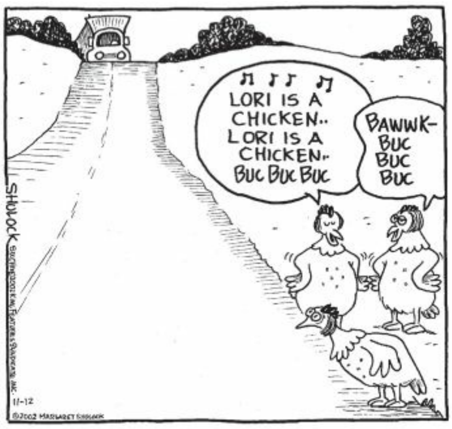
Who shall I be today? By varying the way they look, adolescents try out different "selves." Although we eventually form a consistent and stable sense of identity, the self we present may change with the situation.

These are the years when many people in industrialized countries begin exploring new opportunities by attending college or working full time. Many college seniors have achieved a clearer identity and a more positive self-concept than they had as first-year students (Waterman, 1988). Those students who have achieved a clear sense of identity are less prone to alcohol misuse (Bishop et al., 2005).

Erikson contended that adolescent identity formation (which continues into adulthood) is followed in young adulthood by a developing capacity for **intimacy,** the ability to form emotionally close relationships. When Mihaly Csikszentmihalyi [chick-SENT-me-hi] and Jeremy Hunter (2003) used a beeper to sample the daily experiences of American teens, they found them unhappiest when alone and happiest when with friends. Romantic relationships, which tend to be emotionally intense, are reported by some two in three North American 17-year-olds, but fewer in collectivist countries such as China (Collins et al., 2009; Li et al., 2010). Those who enjoy high-quality (intimate, supportive) relationships with family and friends tend also to enjoy similarly high-quality romantic relationships in adolescence, which set the stage for healthy adult relationships. Such relationships are, for most of us, a source of great pleasure. As Aristotle long ago recognized, we humans are “the social animal.” Relationships matter.

intimacy

in Erikson’s theory, the ability to form close, loving relationships; a primary developmental task in young adulthood.



SIX CHIX © 2002 Margaret Shulock Dist. By King Features Syndicate, World Rights Reserved

Parent and Peer Relationships

52-2 How do parents and peers influence adolescents?

This next research finding will not surprise you: As adolescents in Western cultures seek to form their own identities, they begin to pull away from their parents (Shanahan et al., 2007). The preschooler who can’t be close enough to her mother, who loves to touch and cling to her, becomes the 14-year-old who wouldn’t be caught dead holding hands with Mom. The transition occurs gradually (**Figure 52.1**). By adolescence, parent-child arguments occur more often, usually over mundane things—household chores, bedtime, homework (Tesser et al., 1989). Conflict during the transition to adolescence tends to be greater with first-born than with second-born children, and greater with mothers than with fathers (Burk et al., 2009; Shanahan et al., 2007).

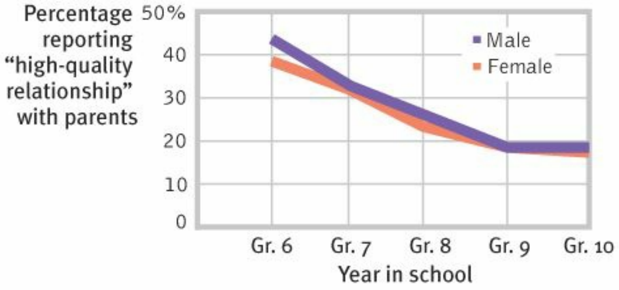


Figure 52.1

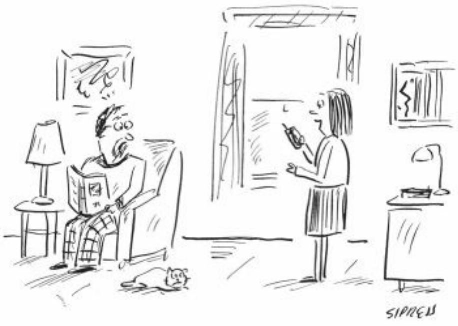
Figure 52.1 The changing parent-child relationship

In a large national study of Canadian families, the typically close, warm relationships between children and their parents loosened as they became teens (Pepler & Craig, 2012).



David Sipress

“She says she’s someone from your past who gave birth to you, and raised you, and sacrificed everything so you could have whatever you wanted.”

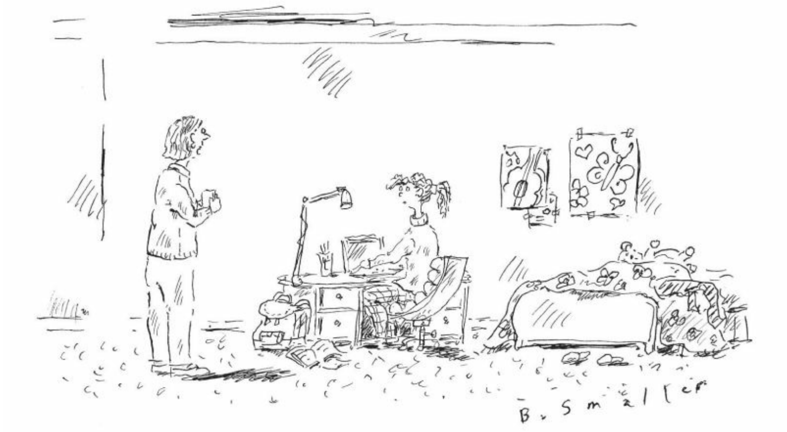
> “*I love u guys.*”
>
> *Emily Keyes’ final text message to her parents before dying in a Colorado school shooting, 2006*

For a minority of parents and their adolescents, differences lead to real splits and great stress (Steinberg & Morris, 2001). But most disagreements are at the level of harmless bickering. With sons, the issues often are behavior problems, such as acting out or hygiene; for daughters, the issues commonly involve relationships, such as dating and friendships (Schlomer et al., 2011). Most adolescents—6000 of them surveyed in 10 countries, from Australia to Bangladesh to Turkey—have said they like their parents (Offer et al., 1988). “We usually get along but . . . ,” adolescents often reported (Galambos, 1992; Steinberg, 1987).

Positive parent-teen relations and positive peer relations often go hand in hand. High school girls who had the most affectionate relationships with their mothers tended also to enjoy the most intimate friendships with girlfriends (Gold & Yanof, 1985). And teens who felt close to their parents have tended to be healthy and happy and to do well in school (Resnick et al., 1997). Of course, we can state this correlation the other way: Misbehaving teens are more likely to have tense relationships with parents and other adults.

Adolescence is typically a time of diminishing parental influence and growing peer influence. Asked in a survey if they had “ever had a serious talk” with their child about illegal drugs, 85 percent of American parents answered *Yes*. But if the parents had indeed given this earnest advice, many teens had apparently tuned it out: Only 45 percent could recall such a talk (Morin & Brossard, 1997).

Heredity does much of the heavy lifting in forming individual temperament and personality differences, and peer influences do much of the rest. When with peers, teens discount the future and focus more on immediate rewards (O’Brien et al., 2011). Most teens are herd animals. They talk, dress, and act more like their peers than their parents. What their friends are, they often become, and what “everybody’s doing,” they often do. Teens’ social media use illustrates the power of peer influence. Compared to photos with few likes, teens prefer photos with many other likes—even photos of risky behaviors such as marijuana smoking. Moreover, when viewing many-liked photos, teens’ brains become more active in areas associated with reward processing and imitation (Sherman et al., 2016). Liking and doing what everybody else likes and does feels good.



Barbara Smaller The New Yorker Collection/The Cartoon Bank

“It’s you who don’t understand me—I’ve been fifteen, but you have never been forty-eight.”

Part of what everybody’s doing is networking—a lot. U.S. teens typically send 30 text messages daily and average 145 Facebook friends (Lenhart, 2015). They tweet, post videos to Snapchat, and share pictures on Instagram. Online communication stimulates intimate self-disclosure—both for better (support groups) and for worse (online predators and extremist groups) (Subrahmanyam & Greenfield, 2008; Valkenburg & Peter, 2009; Wilson et al., 2012).

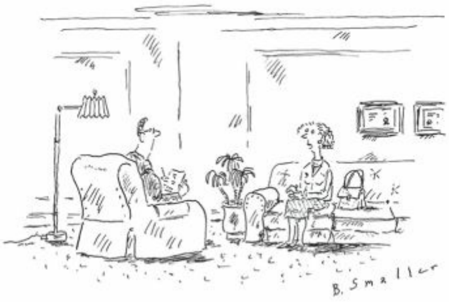
“I’m fourteen, Mom, I don’t do hugs.”

Both online and in real life, for those who feel excluded and bullied by their peers, the pain is acute. Most excluded “students suffer in silence. . . . A small number act out in violent ways against their classmates” (Aronson, 2001). The pain of exclusion also persists. In one large study, those who were bullied as children showed poorer physical health and greater psychological distress 40 years later (Takizawa et al., 2014).

So, for adolescents, peer approval matters. Yet in other ways, parental approval matters, too. Teens have seen their parents as influential in shaping their religious faith and in thinking about college and career choices (*Emerging Trends*, 1997). Most adolescents identify with their parents’ political views (Ojeda & Hatemi, 2015).



Barbara Smaller/Funny Times

“First, I did things for my parents’ approval, then I did things for my parents’ disapproval, and now I don’t know why I do things.”

Emerging Adulthood

52-3 What is *emerging adulthood*?

In the Western world, adolescence now roughly corresponds to the teen years. At earlier times, and in other parts of the world today, this slice of life has been much smaller (Baumeister & Tice, 1986). Shortly after sexual maturity, young people would assume adult responsibilities and status. The event might be celebrated with an elaborate initiation—a public rite of passage. The new adult would then work, marry, and have children.

When schooling became compulsory in many Western countries, independence was put on hold until after graduation. Adolescents are now taking more time to establish themselves as adults. In the United States, for example, the average age at first marriage has increased more than 5 years since 1960, to 29 for men, and 27 for women. In 1960, three in four women and two in three men had, by age 30, finished school, left home, become financially independent, married, and had a child. In the early twenty-first century, fewer than half of 30-year-old women and one-third of 30-year-old men were meeting these five milestones (Henig, 2010).

Together, later independence and earlier sexual maturity have widened the once-brief interlude between biological maturity and social independence (**Figure 52.2**). In prosperous communities, the time from 18 to the mid-twenties is an increasingly not-yet-settled phase of life, now often called **emerging adulthood** (Arnett, 2006, 2007; Reitzle, 2006). No longer adolescents, these emerging adults, having not yet assumed full adult responsibilities and independence, feel “in between.” After high school, those who enter the job market or go to college may be managing their own time and priorities. Yet they may be doing so from their parents’ home, unable to afford their own place and perhaps still emotionally dependent as well. Recognizing today’s more gradually emerging adulthood, the U.S. government now allows dependent children up to age 26 to remain on their parents’ health insurance (Cohen, 2010).

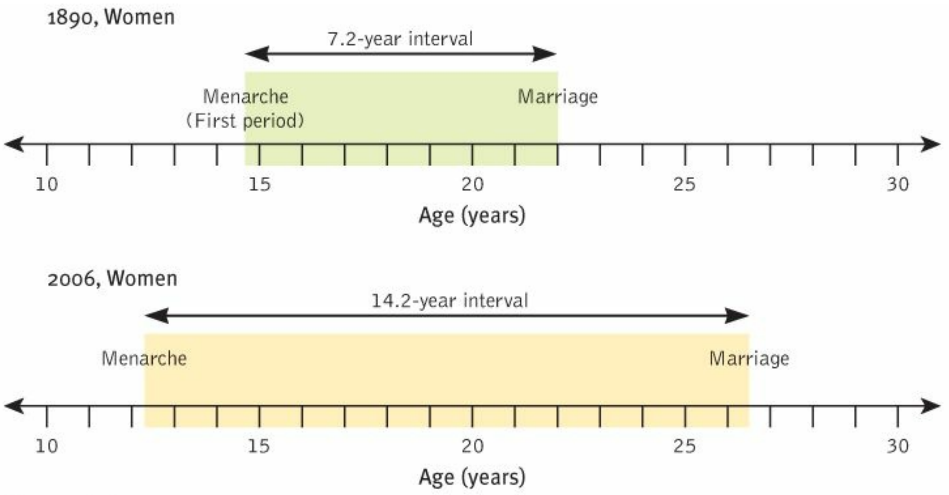


Figure 52.2
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 52.2 The transition to adulthood is being stretched from both ends

In the 1890s, the average interval between a woman's first menstrual period and marriage, which typically marked a transition to adulthood, was about 7 years. By 2006 in industrialized countries, that gap had widened to about 14 years (Finer & Philbin, 2014; Guttmacher Institute, 1994). Although many adults are unmarried, later marriage combines with prolonged education and earlier menarche to help stretch out the transition to adulthood.

emerging adulthood

a period from about age 18 to the mid-twenties, when many in Western cultures are no longer adolescents but have not yet achieved full independence as adults.

✓ Check Your Understanding

Ask Yourself

- What have been your best and worst experiences during adolescence? How have your experiences been influenced by environmental factors, such as your cultural context, and how have they been influenced by your inborn traits?

Test Yourself

- How has the transition from childhood to adulthood changed in Western cultures in the last century or so?
- Match the psychosocial development stage (1–8) with the issue that Erikson believed we wrestle with at that stage (a–h).

1. Infancy
2. Toddlerhood
3. Preschool
4. Elementary school
5. Adolescence
6. Young adulthood
7. Middle adulthood
8. Late adulthood

a. Generativity vs. stagnation
b. Integrity vs. despair
c. Initiative vs. guilt
d. Intimacy vs. isolation
e. Identity vs. role confusion
f. Competence vs. inferiority
g. Trust vs. mistrust
h. Autonomy vs. shame and doubt

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 52 REVIEW

52-1 What are the social tasks and challenges of adolescence?

- Erikson theorized that each life stage has its own psychosocial task, and that a chief task of adolescence is solidifying one's sense of self—one's *identity*. This often means "trying on" a number of different roles.
- *Social identity* is the part of the self-concept that comes from a person's group memberships.
- Erikson believed that adolescent identity formation is followed in young adulthood by a developing capacity for *intimacy*.

52-2 How do parents and peers influence adolescents?

- During adolescence, parental influence diminishes and peer influence increases.
- Most adolescents adopt their peers' ways of dressing, acting, and communicating.
- Parents have more influence in religion, politics, and college and career choices.

52-3 What is *emerging adulthood*?

- Due to earlier sexual maturity and later independence, the transition from adolescence to adulthood is taking longer than in the past.
- *Emerging adulthood* is the period from age 18 to the mid-twenties, when many young people are not yet fully independent. This stage is found mostly in today's Western cultures.

Multiple-Choice Questions

1. In many Western societies, it is common for adolescents to graduate from high school, go to college, and still live at home with their parents. They have not yet assumed full adult responsibilities and independence. Psychologists have identified this period of time as

a. adulthood.
b. early adulthood.
c. emerging adulthood.
d. late adolescence.
e. role confusion.

2. Which is true of social relations during the teen years?

a. As teens distance themselves from parents, peer relationships become more important.
b. High school girls who have the poorest relationships with their mothers have the most intense friendships with peers.
c. Parental influence peaks during mid to late adolescence.
d. Most adolescents have serious disagreements with parents, leading to great social stress.
e. Teens are generally more concerned with family relationships than peer relationships.

3. According to Erikson, the primary developmental task for adolescents is to develop a sense of

a. trust.
b. initiative.
c. competence.
d. identity.
e. intimacy.

4. Compared with the late nineteenth century, what is true about the transition from childhood to adulthood in Western cultures today?

a. It starts earlier and is completed earlier.
b. It starts later and is completed later.
c. It starts later and is completed earlier.
d. It starts earlier and is completed later.
e. It has not changed.

5. Megan, a third grader, is having trouble with math. She is starting to do poorly in other subjects, because she feels she cannot master math. Based on Erikson’s stages of psychosocial development, which stage is Megan in?

a. Autonomy versus shame and doubt
b. Initiative versus guilt
c. Competence versus inferiority
d. Identity versus role confusion
e. Intimacy versus isolation

Practice FRQs

1. What is emerging adulthood? Describe two trends that have led researchers to consider this an additional stage of life.

Answer

1 point: Emerging adulthood is the period in modern Western cultures during the late teens to the mid-twenties that bridges the gap between adolescent dependence and adult independence. Page 542

2 points: Longer years of schooling, and later age of marriage and moving out of the family home, are the trends that have led to recognition of this new stage. Page 543

2. Describe Erik Erikson’s stages of psychosocial development for each of the following:

- Marek, age 1
- Jessa, age 24
- Pauline, age 50
- Elsie, age 85

(4 points)

Module **53 Sexual Development**

LEARNING TARGETS

- 53-1 Describe how sex hormones influence prenatal and adolescent sexual development, and explain *intersex* conditions.
- 53-2 Discuss the factors that reduce the risk of sexually transmitted infections.
- 53-3 Discuss the factors that influence teenagers’ sexual behaviors and use of contraceptives.
- 53-4 Synthesize what research has taught us about sexual orientation.

The Nature of Gender: Our Biological Sex

53-1 How do sex hormones influence prenatal and adolescent sexual development, and what is an *intersex* condition?

In most physical ways—regulating heat with sweat, preferring energy-rich foods, growing calluses where the skin meets friction—men and women are similar. When looking for a mate, men and women also prize many of the same traits—someone who is kind, honest, and intelligent. But in some mating-related domains, as we will see, males tend to differ from females whether they're chimpanzees or elephants, rural peasants or corporate presidents (Geary, 2010).

In two ways, biology *influences* our gender psychology:

- *Genetically*—males and females have differing *sex chromosomes.*
- *Physiologically*—males and females have differing concentrations of *sex hormones*, which trigger other anatomical differences.

These two influences began to form you long before you were born.

Prenatal Sexual Development

Six weeks after you were conceived, you and someone of the other sex looked much the same. Then, as your genes kicked in, your biological sex—determined by your twenty-third pair of chromosomes (the two sex chromosomes)—became more apparent. Whether you are male or female, your mother's contribution to that chromosome pair was an **X chromosome.** From your father, you received the 1 chromosome out of 46 that is not unisex—either another X chromosome, making you female, or a **Y chromosome,** making you male.

X chromosome

the sex chromosome found in both males and females. Females typically have two X chromosomes; males typically have one. An X chromosome from each parent produces a female child.

Y chromosome

the sex chromosome typically found only in males. When paired with an X chromosome from the mother, it produces a male child.

About 7 weeks after conception, a single gene on the Y chromosome throws a master switch, which triggers the testes to develop and to produce **testosterone,** the main androgen (male hormone) that promotes male sex organ development. (Females also have testosterone, but less of it.)

testosterone

the most important male sex hormone. Both males and females have it, but the additional testosterone in males stimulates the growth of the male sex organs during the fetal period, and the development of the male sex characteristics during puberty.

Later, during the fourth and fifth prenatal months, sex hormones bathe the fetal brain and influence its wiring. Different patterns for males and females develop under the influence of the male's greater testosterone and the female's ovarian hormones (Hines, 2004; Udry, 2000). If, however, females are prenatally exposed to unusually high levels of male hormones, they tend to grow up with more male-typical activity interests (Endendijk et al., 2016). Prenatal hormones help sculpt what we love to do.

Adolescent Sexual Development

A flood of hormones triggers another period of dramatic physical change during adolescence, when boys and girls enter puberty. In this two-year period of rapid sexual maturation, pronounced male-female differences emerge. A variety of changes begin at about age 11 in girls and at about age 12 in boys, though the subtle beginnings of puberty, such as enlarging testes, appear earlier (Herman-Giddens et al., 2012). A year or two before the physical changes are visible, girls and boys often feel the first stirrings of physical attraction (McClintock & Herdt, 1996).

Girls' slightly earlier entry into puberty can at first propel them to greater height than boys of the same age (**Figure 53.1**). But boys catch up when they begin puberty, and by age 14, they are usually taller than girls. During these growth spurts, the **primary sex characteristics**—the reproductive organs and external genitalia—develop dramatically. So do the nonreproductive **secondary sex characteristics**. Girls develop breasts and larger hips. Boys' facial hair begins growing and their voices deepen. Pubic and underarm hair emerges in both girls and boys (**Figure 53.2**).

Figure 53.2 Body changes at puberty

At about age 11 in girls and age 12 in boys, a surge of hormones triggers a variety of visible physical changes.

FYI

Pubertal boys may not at first like their sparse beard. (But then it grows on them.)

For boys, puberty's landmark is the first ejaculation, which often occurs first during sleep (as a "wet dream"). This event, called **spermarche**, usually happens by about age 14.

spermarche

[sper-MAR-key] the first ejaculation.

In girls, the landmark is the first menstrual period, **menarche,** usually within a year of age 12½ (Anderson et al., 2003). Genes play a major role in predicting when girls experience menarche (Perry et al., 2014). But environment matters, too. Early menarche is more likely following stresses related to father absence, sexual abuse, insecure attachments, or a history of a mother's smoking during pregnancy (Rickard et al., 2014; Shrestha et al., 2011; Sung et al., 2016). As we saw in Module 51, girls are developing breasts and reaching puberty earlier than in the past.

menarche

[meh-NAR-key] the first menstrual period.

Girls prepared for menarche usually view it as a positive life transition (Chang et al., 2009). Males report mostly positive emotional reactions to spermarche (Fuller & Downs, 1990).

Sexual Development Variations

Nature may blur the biological line between males and females. **Intersex** individuals are born with unusual combinations of male and female chromosomes, hormones, and anatomy. For example, a genetic male may be born with normal male hormones and testes but no penis or a micropenis. Such individuals may struggle with their gender identity.

intersex

a condition present at birth due to unusual combinations of male and female chromosomes, hormones, and anatomy; possessing biological sexual characteristics of both sexes.

In the past, medical professionals often recommended *sex-reassignment surgery* to create an unambiguous sex identity for some children with this condition. One study reviewed 14 cases of genetic boys who had undergone early surgery and been raised as girls. Of those cases, 6 had later identified as male, 5 were living as females, and 3 reported an unclear male or female identity (Reiner & Gearhart, 2004).

In one famous case, a little boy lost his penis during a botched circumcision. His parents followed a psychiatrist's advice to raise him as a girl rather than as a damaged boy. So, with male chromosomes and hormones and female upbringing, did nature or nurture form this child's gender identity? Although raised as a girl, "Brenda" Reimer was not like most other girls. "She" didn't like dolls. She tore her dresses with rough-and-tumble play. At puberty she wanted no part of kissing boys. Finally, Brenda's parents explained what had happened, whereupon Brenda immediately rejected the assigned female identity. He cut his hair and chose a male name, David. He eventually married a woman and became a stepfather. Sadly, he later committed suicide (Colapinto, 2000). Today, experts generally recommend postponing any sex-reassignment surgery until a child's naturally developing physical appearance and gender identity become clear.

Semenya

Michael Dalder/SEMENYA Reuters/Newscom

"I am who I am." Dramatic improvements in South African track star Caster Semenya's race times prompted the International Association of Athletics Federations to undertake sex testing in 2009. Semenya was reported to have physical characteristics not typically male or female. She was officially cleared to continue competing as a woman. Semenya declared, "God made me the way I am and I accept myself. I am who I am" (YOU, 2009). In 2016, she won an Olympic gold medal.

The bottom line: "Sex matters," concluded the National Academy of Sciences (2001). Sex-related genes and physiology "result in behavioral and cognitive differences between males and females." Yet, as we will see, environmental factors matter, too. Nature and nurture work together.

Sexually Transmitted Infections

53-2 How can sexually transmitted infections be prevented?

Every day, more than 1 million people worldwide acquire a *sexually transmitted infection* (*STI;* also called *STD,* for *sexually transmitted disease*) (WHO, 2013). “Compared with older adults,” reports the Centers for Disease Control (CDC, 2016), “sexually active adolescents aged 15–19 years and young adults aged 20–24 years are at higher risk.” Teenage girls, for example, are at heightened risk given their not fully mature anatomy and lower levels of protective antibodies (Dehne & Riedner, 2005; Guttmacher Institute, 1994).

Condoms offer only limited protection against certain skin-to-skin STIs, such as herpes, but they do reduce other risks (NIH, 2001). The effects were clear when Thailand promoted condom use by commercial sex workers. Over a 4-year period, as condom use soared from 14 to 94 percent, the annual number of bacterial STIs plummeted from 410,406 to 27,362 (WHO, 2000). When used by people with an infected partner, condoms also have been 80 percent effective in preventing transmission of *HIV* (*human immunodeficiency virus*—the virus that causes **AIDS**) (Weller & Davis-Beaty, 2002; WHO, 2003). Although HIV can be transmitted by other means, such as needle sharing during drug use, its sexual transmission is most common. Half of all humans with HIV (and one fourth of Americans with HIV) are women.

AIDS (acquired immune deficiency syndrome)

a life-threatening, sexually transmitted infection caused by the *human immunodeficiency virus (HIV).* AIDS depletes the immune system, leaving the person vulnerable to infections.

AIDS’ long incubation period means that many were infected in their teens and twenties. In 2012, the death of 1.6 million people with AIDS worldwide left behind countless grief-stricken loved ones, including millions of orphaned children (UNAIDS, 2013). In sub-Saharan Africa, home to two-thirds of those with HIV, medical treatment to extend life and care for the dying is sapping needed resources.

Having one sexual partner means also partnering with that partner's past partners—any one of whom might have unknowingly transmitted an STI. Hence, the first step in preventing STIs is knowing one's status, and sharing it with one's sexual partner.

Sexual Risk Taking and Teen Pregnancy

53-3 What factors influence teenagers’ sexual behaviors and use of contraceptives?

Sexual attitudes and behaviors vary dramatically across cultures and eras. “Sex between unmarried adults” is “morally unacceptable,” agree 97 percent of Indonesians and 6 percent of Germans (Pew, 2014). And thanks to decreased sexual activity and increased protection, American teen pregnancy rates are declining (CDC, 2016; Twenge et al., 2016).

Frank Schuermann/Newscom

Keeping abreast of hypersexuality An analysis of the 60 top-selling video games found 489 characters, 86 percent of whom were males (like most of the game players). The female characters were much more likely than the male characters to be “hypersexualized”—partially nude or revealingly clothed, with large breasts and tiny waists (Downs & Smith, 2010). Such depictions can lead to unrealistic expectations about sexuality and contribute to the early sexualization of girls. The American Psychological Association suggests countering this by teaching girls to “value themselves for who they are rather than how they look” (APA, 2007).

So, what produces variations in teen sexuality? Twin studies show that genes influence teen sexual behavior—by influencing pubertal development and hormone levels. But what environmental factors contribute?

Communication about birth control Many teenagers are uncomfortable discussing contraception with parents, partners, and peers. But teens who talk freely and openly with their parents and with their partner in an exclusive relationship are more likely to use contraceptives (Aspy et al., 2007; Milan & Kilmann, 1987).

Impulsivity Among sexually active 12- to 17-year-old American girls, 72 percent said they regretted having had sex (Reuters, 2000). If passion overwhelms intentions (either to use contraceptives or to delay having sex), unplanned sexual activity may result in pregnancy (Ariely & Loewenstein, 2006; MacDonald & Hynie, 2008).

Alcohol use Among late teens and young adults, most sexual hook-ups (casual encounters outside of a relationship) occur after alcohol use, often without knowing consent (Fielder et al., 2013; Garcia et al., 2013; Johnson & Chen, 2015). Those who use alcohol prior to sex are less likely to use condoms (Kotchick et al., 2001). By depressing the brain centers that control judgment, inhibition, and self-awareness, alcohol disarms normal restraints—a phenomenon well known to sexually coercive people.

Mass media Perceived peer norms influence teens' sexual behavior (Lyons et al., 2015; van de Bongardt et al., 2015). Teens pay attention to other teens, who, in turn, are influenced by popular media. Media help write the *social scripts* that affect our perceptions and actions. The more sexual content adolescents and young adults view or read (even when controlling for other predictors of early sexual activity), the more likely they are to perceive their peers as sexually active, to develop sexually permissive attitudes, and to experience early intercourse (Escobar-Chaves et al., 2005; Kim & Ward, 2012; Parkes et al., 2013). One study asked more than a thousand 12- to 14-year-olds what movies they had seen, and then after age 18 asked them about their sexual experiences (O'Hara et al., 2012). After controlling for various adolescent and family characteristics, the more the adolescents viewed movies with high sexual content, the greater was their sexual risk taking—with earlier first sex, more partners, and inconsistent condom use.

Several factors predict sexual restraint:

- **HIGH INTELLIGENCE.** Teens with high rather than average intelligence test scores more often delayed sex, partly because they considered possible negative consequences and were more focused on future achievement than on here-and-now pleasures (Harden & Mendle, 2011).
- **RELIGIOUS ENGAGEMENT.** Actively religious teens more often reserve sexual activity for adulthood or long-term relationships (Hull et al., 2011; Schmitt & Fuller, 2015; Štulhofer et al., 2011).
- **FATHER PRESENCE.** In studies that followed hundreds of New Zealand and U.S. girls from age 5 to 18, having Dad around has reduced the risk of teen pregnancy and of sexual activity before age 16 (Ellis et al., 2003). These associations held even after adjusting for other influences, such as poverty. Close family attachments—as in families that eat together and where parents know their teens' activities and friends—also predict later sexual initiation (Coley et al., 2008).
- **SERVICE LEARNING PARTICIPATION.** Several experiments have found that teens volunteering as tutors or teachers' aides, or participating in community projects, had lower pregnancy rates than did comparable teens randomly assigned to control conditions (Kirby, 2002; O'Donnell et al., 2002). Researchers are unsure why. Does service learning promote a sense of personal competence, control, and responsibility? Does it encourage more future-oriented thinking? Or does it simply reduce opportunities for unprotected sex? (Later school start times and after-school activities also reduced unplanned pregnancies [Bryan et al., 2016; Steinberg, 2015].)

✓ Check Your Understanding

Ask Yourself

- What do you think would be an effective strategy for reducing teen pregnancy?

Test Yourself

- Prenatal sexual development begins about __________ weeks after conception. Adolescence is marked by the onset of _____________.
- From a biological perspective, HIV is passed more readily from women to men than from men to women. True or false?
- Which THREE of the following five factors contribute to unplanned teen pregnancies?

  a. Alcohol use
  b. Higher intelligence level
  c. Father absence
  d. Mass media models
  e. Participating in service learning programs

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Sexual Orientation

53-4 What has research taught us about sexual orientation?

We express the *direction* of our sexual interest in our **sexual orientation**—which usually is our enduring sexual attraction toward members of our own sex *(homosexual orientation)* or the other sex *(heterosexual orientation)*. Other variations include an attraction to both sexes *(bisexual orientation)*. We experience our sexual orientation in our interests, thoughts, and fantasies.

sexual orientation

our enduring sexual attraction, usually toward members of our own sex (homosexual orientation) or the other sex (heterosexual orientation); variations include attraction toward both sexes (bisexual orientation).

Across time and place, cultures vary in their attitudes toward same-sex attractions. Same-sex sexual activity is "not wrong at all," said 11 percent of Americans in 1973, and 50 percent in 2016 (GSS, 2017). "Should society accept homosexuality?" *Yes*, say 88 percent of Spaniards and 1 percent of Nigerians, with women everywhere being more accepting than men (Pew, 2013). Yet whether a culture condemns or accepts same-sex unions, heterosexuality is most common, and bisexuality and homosexuality exist. In most African countries, same-sex relationships are illegal. Yet the ratio of lesbian, gay, or bisexual people "is no different from other countries in the rest of the world," reports the Academy of Science of South Africa (2015). What is more, same-sex activity spans human history, from the prehistoric rock art era to the present.

FYI

As explained in Module 49, sexual orientation is distinct from gender identity (including transgender identity).

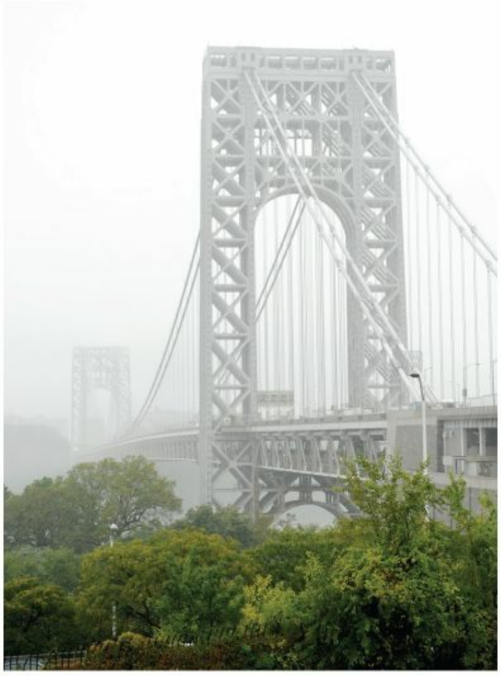
How many people are exclusively homosexual? According to more than a dozen national surveys in Europe and the United States, about 3 or 4 percent of men and 2 percent of women (Chandra et al., 2011; Herbenick et al., 2010; Savin-Williams et al., 2012). When the U.S. National Center for Health Statistics asked 34,557 Americans about their sexual identity, they found that all but 3.4 percent answered "straight," with 1.6 percent answering "gay" or "lesbian" and 0.7 percent saying "bisexual" (Ward et al., 2014). In a follow-up survey, 1.6 percent of women and 2.3 percent of men anonymously reported feeling "mostly" or "only" same-sex attraction (Copen et al., 2016). A larger number of adults—13 percent of women and 5 percent of men—report some same-sex sexual contact during their lives (Chandra et al., 2011). In less tolerant places, people are more likely to hide their sexual orientation (though they are no less likely to seek out same-sex content and partners, as evidenced by Google searches and Craigslist ads). About 3 percent of California men express a same-sex preference on Facebook, for example, as do only about 1 percent in Mississippi (MacInnis & Hodson, 2015; Stephens-Davidowitz, 2013).

FYI

In one British survey, of the 18,876 people contacted, 1 percent were seemingly asexual, having "never felt sexually attracted to anyone at all" (Bogaert, 2004, 2006).

What does it feel like to have same-sex attractions in a majority heterosexual culture? If you are heterosexual, imagine how you would feel if you were socially isolated for openly admitting or displaying your feelings. How would you react if you overheard people making crude jokes about heterosexual people, or if most movies, TV shows, and advertisements portrayed (or implied) homosexuality? And how would you answer if your family members were pleading with you to change your heterosexual "lifestyle" and to enter into a homosexual marriage?

Facing such reactions, some individuals struggle with their sexual attractions, especially during adolescence and if feeling rejected by parents or harassed by peers. If lacking social support, nonheterosexual teens may have lower self-esteem, higher anxiety and depression, and an increased risk of contemplating suicide (Becker et al., 2014; Lyons, 2015; Wang, J. et al., 2012, 2015). They may at first try to ignore or deny their desires, hoping they will go away. But they don't. They may try to change their orientation through psychotherapy, willpower, or prayer. But the feelings typically persist, as do those of heterosexual people—who are similarly incapable of change (Haldeman, 1994, 2002; Myers & Scanzoni, 2005).



STAN HONDA/Getty Images

Driven to suicide In 2010, Rutgers University student Tyler Clementi jumped off this bridge after his roommate secretly filmed, shared, and tweeted about Clementi's intimate encounter with another man. Reports then surfaced of other gay teens who had reacted in a similarly tragic fashion after being taunted. Since 2010, Americans—especially those under 30—have been increasingly supportive of those with same-sex orientations.

The prevalence of harmful anti-gay stereotypes can also contribute to the isolation and rejection that many nonheterosexual people feel. One such stereotype is that homosexual men are at risk for molesting children (Herek, 2016). But research shows that most men are sexually responsive either to adult women (if straight) or to adult men (if gay), and that some others—many fewer—instead exhibit *pedophilia,* a disordered attraction to young boys or girls (Blanchard et al., 2012; Dreger, 2011).

Today's psychologists view sexual orientation as neither willfully chosen nor willfully changed. Sexual orientation in some ways is like handedness: Most people are one way, some the other. A very few are truly ambidextrous. Regardless, the way one is endures. "Efforts to change sexual orientation are unlikely to be successful and involve some risk of harm," declared a 2009 American Psychological Association report. Recognizing this, in 2016, Malta became the first European country to outlaw the controversial practice of "conversion therapy," which aims to change people's gender identities or sexual orientations. Several U.S. states have likewise banned sexual conversion therapy with minors.

Sexual orientation is especially persistent for men. Women's sexual orientation tends to be less strongly felt and, for some women, is more fluid and changing (Dickson et al., 2013; Norris et al., 2015). In general, men are sexually simpler. Men's lesser sexual variability is apparent in many ways (Baumeister, 2000). Across time, across cultures, across situations, and across differing levels of education, religious observance, and peer influence, men's sexual drive and interests are less flexible and varying than are adult women's. Women, for example, more often prefer to alternate periods of high sexual activity with periods of almost none (Mosher et al., 2005). Baumeister calls this flexibility *erotic plasticity*.

Environment and Sexual Orientation

So, our sexual orientation seems to be something we do not choose and (especially for males) cannot change. Where, then, do these preferences come from? See if you can anticipate the conclusions that have emerged from hundreds of research studies by responding *Yes* or *No* to the following questions:

1. Is homosexuality linked with a child's problematic relationships with parents, such as with a domineering mother and an ineffectual father, or a possessive mother and a hostile father?

2. Does homosexuality involve a fear or hatred of people of the other sex, leading individuals to direct their desires toward members of their own sex?
3. Is sexual orientation linked with sex hormone levels currently in the blood?
4. As children, were most homosexuals molested, seduced, or otherwise sexually victimized by an adult homosexual?

The answer to all these questions has been *No* (Storms, 1983). In a search for possible environmental influences on sexual orientation, Kinsey Institute investigators interviewed nearly 1000 homosexuals and 500 heterosexuals. They assessed nearly every imaginable psychological cause of homosexuality—parental relationships, childhood sexual experiences, peer relationships, dating experiences (Bell et al., 1981; Hammersmith, 1982). Their findings: Homosexuals are no more likely than heterosexuals to have been smothered by maternal love or neglected by their father. In one national survey of nearly 35,000 adults, those with a same-sex attraction were somewhat more likely to report having experienced child sexual abuse. But 86 percent of the men and 75 percent of the women with same-sex attraction reported no such abuse (Roberts et al., 2013).

And consider this: If “distant fathers” were more likely to produce homosexual sons, then shouldn’t boys growing up in father-absent homes more often be gay? (They are not.) And shouldn’t the rising number of such homes have led to a noticeable increase in the gay population? (It has not.) Most children raised by gay or lesbian parents grow up straight (Gartrell & Bos, 2010). And they grow up within the normal range of healthfulness and emotional well-being (Bos et al., 2016).

Imagine that a mad scientist pitted nature against nurture by, at birth, changing a group of boys into girls—by castrating them, thus surgically feminizing them, and then raising them as girls. Surely this would socialize these “girls” into becoming attracted to males? In seven famous cases, this actually has happened, sometimes as a surgical procedure after the accidental severing of a penis during surgery. In each case, the result was a person attracted to *women*—just “the result we would expect if male sexual orientation were entirely due to nature,” concluded a consensus statement by sexual orientation experts (Bailey et al., 2016).

So, what else might influence sexual orientation? Could a same-sex experience have an effect? Even in tribal cultures in which homosexual behavior is expected of all boys before marriage, most men are heterosexual (Hammack, 2005; Money, 1987). (As this illustrates, homosexual *behavior* does not always indicate a homosexual *orientation.*) Moreover, though peers’ attitudes predict teens’ sexual attitudes and behavior, they do not predict same-sex attraction. “Peer influence has little or no effect” on sexual orientation (Brakefield et al., 2014).

FYI

Note that the scientific question is not “What causes homosexuality?” (or “What causes heterosexuality?”) but “What causes differing sexual orientations?” In pursuit of answers, psychological science compares the backgrounds and physiology of people whose sexual orientations *differ*.

The bottom line from a half-century’s theory and research: If there are environmental factors that influence sexual orientation after we’re born, we do not yet know what they are.

Biology and Sexual Orientation

The seeming absence of environmental influences on sexual orientation has motivated researchers to explore possible biological influences. They have considered

- evidence of same-sex behaviors in other species,
- gay-straight brain differences,
- genetics, and
- prenatal hormones.

Same-Sex Attraction in Other Species

In Boston's Public Gardens, caretakers solved the mystery of why a much-loved swan couple's eggs never hatched. Both swans were female. In New York City's Central Park Zoo, penguins Silo and Roy spent several years as devoted same-sex partners. Same-sex sexual behaviors have also been observed in several hundred other species, including grizzlies, gorillas, monkeys, flamingos, and owls (Bagemihl, 1999). Among rams, for example, some 7 to 10 percent display same-sex attraction by shunning ewes and seeking to mount other males (Perkins & Fitzgerald, 1997). Homosexual behavior seems a natural part of the animal world.

Gay-Straight Brain Differences

Researcher Simon LeVay (1991) studied sections of the hypothalamus taken from deceased heterosexual and homosexual people. As a gay scientist, LeVay wanted to do "something connected with my gay identity." To avoid biasing the results, he did a *blind study*, not knowing which donors were gay. For nine months he peered through his microscope at a cell cluster that varied in size among donors. Then, one morning, he broke the code: One cell cluster was reliably larger in heterosexual men than in women and homosexual men. "I was almost in a state of shock," LeVay said (1994). "I took a walk by myself on the cliffs over the ocean. I sat for half an hour just thinking what this might mean."

It should not surprise us that in other ways, too, brains differ with sexual orientation (Bao & Swaab, 2011; Savic & Lindström, 2008). Remember our maxim: *Everything psychological is simultaneously biological*. But when do such brain differences begin? At conception? In the womb? During childhood or adolescence? Does experience produce these differences? Or is it genes or prenatal hormones (or genes activating prenatal hormones)?

LeVay does not view the hypothalamus as a sexual orientation center; rather, he sees it as an important part of the neural pathway engaged in sexual behavior. He acknowledges that sexual behavior patterns may influence the brain's anatomy. In fish, birds, rats, and humans, brain structures vary with experience—including sexual experience, reports sex researcher Marc Breedlove (1997). But LeVay believes it more likely that brain anatomy influences sexual orientation. His hunch seems confirmed by the discovery of a similar hypothalamic difference between the male sheep that do and don't display same-sex attraction (Larkin et al., 2002; Roselli et al., 2002, 2004). Moreover, such differences seem to develop soon after birth, or perhaps even before birth (Rahman & Wilson, 2003).

Boston Globe/Getty Images

Juliet and Juliet Boston's beloved swan couple, "Romeo and Juliet," were discovered actually to be, as are many other animal partners, a same-sex pair.

Responses to hormone-derived sexual scents also point to a brain difference (Savic et al., 2005). When straight women were given a whiff of a scent derived from men's sweat, their hypothalamus activated in an area governing sexual arousal. Gay men's brains responded similarly to the men's scent. But straight men's brains showed the arousal response only to a female hormone derivative. Other studies of brain responses to sex-related sweat odors and to pictures of male and female faces have found similar gay-straight differences, including differing responses between lesbians and straight women (Kranz & Ishai, 2006; Martins et al., 2005). Researcher Qazi Rahman (2015) sums it up: Compared with heterosexuals, "gay men appear, on average, more 'female typical' in brain pattern responses and lesbian women are somewhat more 'male typical.'"

Genetic Influences

Evidence indicates that "about a third of variation in sexual orientation is attributable to genetic influences" (Bailey et al., 2016). A same-sex orientation does have some tendency to run in families. And identical twins are somewhat more likely than fraternal twins to share a homosexual orientation (Alanko et al., 2010; Långström et al., 2010). Because sexual orientations differ in many identical twin pairs, especially female twins, we know that other factors besides genes are also at work—including, it appears, epigenetic marks that help distinguish gay and straight identical twins (Balter, 2015).

By genetic manipulations, experimenters have created female fruit flies that pursued other females during courtship, and males that pursued other males (Demir & Dickson, 2005). “We have shown that a single gene in the fruit fly is sufficient to determine all aspects of the flies’ sexual orientation and behavior,” explained Barry Dickson (2005). With humans, it’s likely that multiple genes, possibly in interaction with other influences, shape sexual orientation. A genome-wide study of 409 pairs of gay brothers identified sexual orientation links with areas of two chromosomes, one maternally transmitted (Sanders et al., 2015).

Researchers have speculated about possible reasons why “gay genes” might exist in the human gene pool, given that same-sex couples cannot naturally reproduce. One possible answer is kin selection. Recall from Module 15 the evolutionary psychology reminder that many of our genes also reside in our biological relatives. Perhaps, then, gay people’s genes live on through their supporting the survival and reproductive success of their nieces, nephews, and other relatives. Gay men make generous uncles, suggests one study of Samoans (Vasey & VanderLaan, 2010).

A *fertile females theory* suggests that maternal genetics may also be at work (Bocklandt et al., 2006). Italian studies confirm what others have found—that homosexual men tend to have more homosexual relatives on their mother’s side than on their father’s (Camperio-Ciani et al., 2004, 2009; Camperio-Ciani & Pellizzari, 2012; VanderLaan & Vasey, 2011; VanderLaan et al., 2012). And the relatives on the mother’s side also produce more offspring than do the maternal relatives of heterosexual men. Perhaps the genes that dispose some women to conceive more children with men also dispose some men to be attracted to men (LeVay, 2011). Thus, the decreased reproduction by gay men appears offset by the increased reproduction by their maternal extended family.

Prenatal Influences

Elevated rates of homosexual orientation in identical *and* fraternal twins suggest an influence not only of shared genes but also a shared prenatal environment. Recall that in the womb, sex hormones direct our development as male or female. In animals and some human cases, prenatal hormone conditions have altered a fetus' sexual orientation. German researcher Gunter Dorner (1976, 1988) pioneered research on the influence of prenatal hormones by manipulating a fetal rat's exposure to male hormones, thereby "inverting" its sexual orientation. In other studies, when pregnant sheep were injected with testosterone during a critical period of fetal development, their female offspring later showed homosexual behavior (Money, 1987).

A critical period for the human brain's neural-hormonal control system may exist during the second trimester (Ellis & Ames, 1987; Garcia-Falgueras & Swaab, 2010; Meyer-Bahlburg, 1995). Exposure to the hormone levels typically experienced by female fetuses during this time appears to predispose the person (whether female or male) to be attracted to males in later life. "Prenatal sex hormones control the sexual differentiation of brain centers involved in sexual behaviors," notes Simon LeVay (2011, p. 216). Thus, female fetuses most exposed to testosterone appear most likely later to exhibit gender-atypical traits and experience same-sex desires. (For males, prenatal testosterone exposure, given a sufficient minimum amount, seems not to affect sexual orientation [Breedlove, 2017].)

The mother's immune system may also play a role in the development of sexual orientation. Men with older brothers are somewhat more likely to be gay, report Ray Blanchard (2004, 2008a,b, 2014) and Anthony Bogaert (2003)—about one-third more likely for each additional older brother. If the odds of homosexuality are roughly 2 percent among first sons, they would rise to about 2.6 percent among second sons, 3.5 percent for third sons, and so on for each additional older brother (Bailey et al., 2016; see **Figure 53.3**).

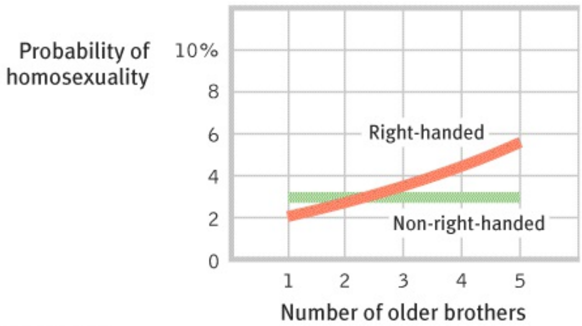


Figure 53.3

Worth Publishers

Figure 53.3 The older brother effect

Researcher Ray Blanchard (2008a) offers these approximate curves depicting a man's likelihood of homosexuality as a function of the number of biological (not adopted) older brothers he has. This correlation has been found in several studies, but only among right-handed men (as about 9 in 10 men are).

The reason for this curious phenomenon—the *older brother* or *fraternal birth-order effect*—is unclear. Blanchard suspects a defensive maternal immune response to foreign substances produced by male fetuses. With each pregnancy with a male fetus, the maternal antibodies may become stronger and may prevent the fetus' brain from developing in a male-typical pattern. Consistent with this biological explanation, the fraternal birth-order effect occurs only in men with older brothers born to the same mother (whether raised together or not). Sexual orientation is unaffected by adoptive brothers (Bogaert, 2006). The birth-order effect on sexual orientation is not found among women with older sisters, women who were womb-mates of twin brothers, and men who are not right-handed (Rose et al., 2002).

Gay-Straight Trait Differences

Comparing the traits of gay and straight people is akin to comparing the heights of men and women. The average man is taller than most women, but many women are taller than most men. And just as knowing someone's height doesn't specify their sex, so also knowing someone's traits doesn't tell you their sexual orientation. Yet on several traits, the average homosexual female or male is intermediate between straight females and males (**Table 53.1**; see also LeVay, 2011; Rahman & Koerting, 2008; Rieger et al., 2016). For example, lesbians’ cochlea and hearing systems develop in a way that is intermediate between those of heterosexual females and heterosexual males, which seems attributable to prenatal hormonal influence (McFadden, 2002). From birth on, gay males tend to be shorter and lighter than straight males, while from birth on, lesbian females tend to be heavier than straight females (Bogaert, 2010; Deputy & Boehmer, 2014; Frisch & Zdravkovic, 2010). Facial structure and fingerprint ridge counts may also differ (Hall & Kimura, 1994; Mustanski et al., 2002; Sanders et al., 2002; Skorska et al., 2015).

TABLE 53.1 Biological Correlates of Sexual Orientation

Gay-straight trait differences

Sexual orientation is part of a package of traits. Studies—some in need of replication—indicate that homosexuals and heterosexuals differ in the following biological and behavioral traits:

- spatial abilities
- fingerprint ridge counts
- auditory system development
- handedness
- occupational preferences
- relative finger lengths
- gender nonconformity
- age of onset of puberty in males
- face structure and birth size/weight
- sleep length
- physical aggression
- walking style

On average (the evidence is strongest for males), results for gays and lesbians fall between those of straight men and straight women. Three biological influences—brain, genetic, and prenatal—may contribute to these differences.

Brain differences

- One hypothalamic cell cluster is smaller in women and gay men than in straight men.
- Gay men’s hypothalamus reacts as does straight women’s to the smell of men’s sex-related hormones.

Genetic influences

- Shared sexual orientation is higher among identical twins than among fraternal twins.
- Sexual attraction in fruit flies can be genetically manipulated.
- Male homosexuality often appears to be transmitted from the mother’s side of the family.

Prenatal influences

- Altered prenatal hormone exposure may lead to homosexuality in humans and other animals.
- Men with several older biological brothers are more likely to be gay, possibly due to a maternal immune-system reaction.

Another you-never-would-have-guessed-it gay-straight difference appears in studies showing that gay men's spatial abilities resemble those typical of straight women (Cohen, 2002; Gladue, 1994; McCormick & Witelson, 1991; Sanders & Wright, 1997). On mental rotation tasks such as the one illustrated in **Figure 53.4**, straight men tend to outscore straight women. (So do women who were womb-mates of a male co-twin [Vuoksimaa et al., 2010].) Researchers find that, as on a number of other measures, the scores of gays and lesbians fall between those of heterosexual males and females (Rahman et al., 2004, 2008). But straight women and gays have both outperformed straight men at remembering objects' spatial locations in memory game tasks (Hassan & Rahman, 2007).

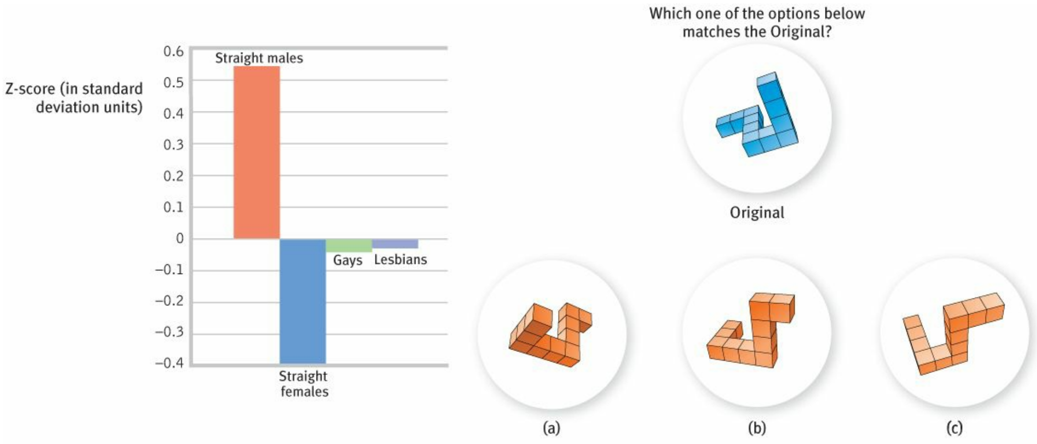

Figure 53.4
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 53.4 Spatial abilities and sexual orientation

Which of the three figures can be rotated to match the original figure at the top? Straight males tend to find this type of mental rotation task easier than do straight females, with gays and lesbians falling in between (Rahman et al., 2004)[1].

***

The consistency of the brain, genetic, and prenatal findings has swung the pendulum toward a biological explanation of sexual orientation (Rahman & Wilson, 2003; Rahma & Koerting, 2008). Still, some people wonder: Should the cause of sexual orientation matter? Perhaps it shouldn't, but people's assumptions matter. If you see sexual orientation as inborn—as shaped by biological and prenatal influences—then you likely favor "equal rights for homosexual and bisexual people" (Bailey et al., 2016). If you see same-sex attraction as a lifestyle choice or as encouraged by social tolerance, then you likely oppose equal rights for nonheterosexual people. To justify his signing a 2014 bill that made some homosexual acts punishable by life in prison, the president of Uganda, Yoweri Museveni, declared that homosexuality is not inborn but rather is a matter of "choice" (Balter, 2014; Landau et al., 2014).

> “*Modern scientific research indicates that sexual orientation is . . . partly determined by genetics, but more specifically by hormonal activity in the womb.*”
>
> *Glenn Wilson and Qazi Rahman,* Born Gay: The Psychobiology of Sex Orientation, *2005*

However, the new biological research is a double-edged sword (Roan, 2010). If sexual orientation, like skin color and sex, is genetically influenced, that does offer a rationale for civil rights protection—though not the only rationale, argue rights advocates (Diamond & Rosky, 2016). Yet this research raises the troubling possibility that genetic markers of sexual orientation could someday be identified through fetal testing, that a fetus could be aborted simply for being predisposed to an unwanted orientation, or that hormonal treatment in the womb might engineer a desired orientation.

> “*There is no sound scientific evidence that sexual orientation can be changed.*”
>
> *UK Royal College of Psychiatrists, 2009*

Check Your Understanding

Ask Yourself

- Based on what you’ve learned so far, how would you say that genes, the brain, hormones, and environment work together to influence sexual development, sexual behavior, and sexual orientation?

Test Yourself

- Which THREE of the following five factors have researchers found to have an effect on sexual orientation?

  a. A domineering mother
  b. The size of a certain cell cluster in the hypothalamus
  c. Prenatal hormone exposure
  d. A distant or ineffectual father
  e. For right-handed men, having multiple older biological brothers

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 53 REVIEW

53-1 How do sex hormones influence prenatal and adolescent sexual development, and what is an *intersex* condition?

- About 7 weeks after conception, a gene on the Y chromosome triggers the production of *testosterone* in males. This promotes male sex organ development.
- During the fourth and fifth prenatal months, sex hormones bathe the fetal brain. Different patterns develop as a result of the male's greater testosterone and the female's ovarian hormones. Prenatal exposure of females to unusually high levels of male hormones can dispose them to more male-typical activity interests later on.
- Another flood of hormones occurs in puberty, triggering a growth spurt, the development of *primary* and *secondary sex characteristics*, and the landmark events of *spermarche* and *menarche.*
- *Intersex* individuals are born with intermediate or unusual combinations of male and female chromosomes, hormones, and anatomy.

53-2 How can sexually transmitted infections be prevented?

- Safer sex practices help prevent sexually transmitted infections (STIs).
- Condoms, while offering limited protection against skin-to-skin STIs, are especially effective in preventing transmission of HIV, the virus that causes *AIDS.*
- Knowing one's STI status and sharing it with one's sexual partner is key to prevention.

53-3 What factors influence teenagers' sexual behaviors and use of contraceptives?

- Sexual behaviors and attitudes vary from culture to culture and era to era.

- Factors contributing to teen pregnancy include minimal communication about birth control with parents, partners, and peers; impulsivity; alcohol use; and mass media influences.
- High intelligence, religious engagement, father presence, and participation in service learning programs have been predictors of teen sexual restraint.

53-4 What has research taught us about sexual orientation?

- *Sexual orientation* is an enduring sexual attraction, usually toward members of one's own sex (homosexual orientation) or the other sex (heterosexual orientation). Variations include attraction toward both sexes (bisexual orientation).
- Today's psychologists view sexual orientation as neither willfully chosen nor willfully changed.
- There is no evidence that environmental influences determine sexual orientation.
- Evidence for biological influences includes the presence of same-sex attraction in many animal species, straight-gay differences in body and brain characteristics, higher rates of homosexuality in certain families and in identical twins, the effect of exposure to certain hormones during critical periods of prenatal development, and the fraternal birth-order effect.

Multiple-Choice Questions

1. A child who is genetically female

- a. has received an X chromosome from her mother and a Y chromosome from her father.
- b. has received a Y chromosome only from her mother.
- c. has received a Y chromosome from her mother and an X chromosome from her father.
- d. has received two X chromosomes from her mother and none from

her father.

e. has received an X chromosome from her father and her mother.

2. Which of the following is a primary sex characteristic that changes at puberty?

a. A growth spurt in height, especially for boys
b. Development of breasts for girls
c. Full development of external genitalia in both sexes
d. Facial hair and deepened voice for boys
e. Appearance of pubic and underarm hair in both sexes

3. Which of the following has been shown to be an effective intervention to reduce teen pregnancies?

a. Abstinence-only sex education in schools
b. Participation in service learning programs
c. Increasing guilt related to sexual activity
d. Taking a pledge to remain abstinent
e. Increased exposure to sexual content in the media

Practice FRQs

1. Provide examples of a primary and a secondary sex characteristic for both males and females.

Answer

1 point: Male primary sex characteristics include growth of penis and testes and first ejaculation (spermarche). Page 546

1 point: Male secondary sex characteristics include body hair and lower voice. Page 546

1 point: Female primary sex characteristics include menarche and full development of external genitalia. Page 546

1 point: Female secondary sex characteristics include body hair, widening of the hips, and growth of breasts. Page 546

2. Explain evidence that suggests a genetic influence on sexual orientation from each of the following types of studies:

- Family studies
- Twin studies
- Animal studies

(3 points)

Module **54 Adulthood: Physical, Cognitive, and Social Development**

LEARNING TARGETS

- 54-1 Identify the physical changes that occur during middle and late adulthood.
- 54-2 Assess how memory changes with age.
- 54-3 Discuss how neurocognitive disorders and Alzheimer's disease affect cognitive ability.
- 54-4 Discuss the themes and influences that mark our social journey from early adulthood to death.
- 54-5 Describe changes in well-being across the life span.
- 54-6 Describe the range of reactions to the death of a loved one.

The unfolding of our lives continues across the life span. It is, however, more difficult to generalize about adulthood stages than about life's early years. If you know that James is a 1-year-old and Jamal is a 10-year-old, you could say a great deal about each child. Not so with adults who differ by a similar number of years. The boss may be 30 or 60; the marathon runner may be 20 or 50; the 19-year-old may be a parent who supports a child or a child who receives an allowance. Yet our life courses are in some ways similar. Physically, cognitively, and especially socially, we differ at age 50 from our 25-year-old selves. In the discussion that follows, we recognize these differences and use three terms: *early adulthood* (roughly twenties and thirties), *middle adulthood* (to age 65), and *late* *adulthood* (the years after 65). Within each of these stages, people will vary widely in physical, psychological, and social development.

Physical Development

54-1 What physical changes occur during middle and late adulthood?

Like the declining daylight after the summer solstice, our physical abilities—muscular strength, reaction time, sensory keenness, and cardiac output—all begin an almost imperceptible decline in our mid-twenties. Athletes are often the first to notice. Baseball players peak at about age 27—with 60 percent of Most Valuable Player awardees since 1985 coming within 2 years of that age (Silver, 2012). But most of us—especially those of us whose daily lives do not require top physical performance—hardly perceive the early signs of decline.

Physical Changes in Middle Adulthood

Athletes over 40 know all too well that physical decline gradually accelerates. As a lifelong basketball player, I [DM] find myself increasingly not racing for that loose ball. But even diminished vigor is sufficient for normal activities. Moreover, during early and middle adulthood, physical vigor has less to do with age than with a person's health and exercise habits. Many physically fit 50-year-olds run four miles with ease, while sedentary 25-year-olds find themselves huffing and puffing up two flights of stairs.

FYI

How old does a person have to be before you think of him or her as old? Depends on who you ask. For 18- to 29-year-olds, 67 was old. For those 60 and over, old was 76 (Yankelovich, 1995).

Aging also brings a gradual decline in fertility, especially for women. For a 35- to 39-year-old woman, the chance of getting pregnant after a single act of intercourse is only half that of a woman 19 to 26 (Dunson et al., 2002). Men experience a gradual decline in sperm count, testosterone level, and speed of erection and ejaculation. Women experience **menopause,** as menstrual cycles end, usually within a few years of age 50. Some may experience distress, as do some men who experience declining virility and physical capacities. But most people age without such problems.

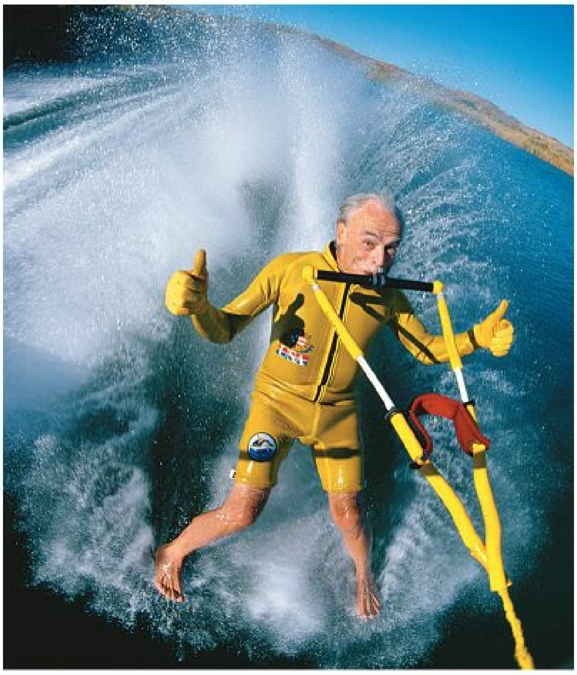
menopause
the time of natural cessation of menstruation; also refers to the biological changes a woman experiences as her ability to reproduce declines.

With age, sexual activity lessens. Nearly 9 in 10 Americans in their late twenties reported having had vaginal intercourse in the past year, compared with 22 percent of women and 43 percent of men over 70 (Herbenick et al., 2010; Reece et al., 2010). Nevertheless, most men and women remain capable of satisfying sexual activity, and most express satisfaction with their sex life. This was true of 70 percent of Canadians surveyed (ages 40 to 64) and 75 percent of Finns (ages 65 to 74) (Kontula & Haavio-Mannila, 2009; Wright, 2006). In one survey, 75 percent of respondents reported being sexually active into their eighties (Schick et al., 2010). And in an American Association of Retired Persons sexuality survey, it was not until age 75 or older that most women and nearly half of men reported little sexual desire (DeLamater, 2012; DeLamater & Sill, 2005). Given good health and a willing partner, the flames of desire, though simmered down, live on. As Alex Comfort (1992, p. 240) jested, “The things that stop you having sex with age are exactly the same as those that stop you riding a bicycle (bad health, thinking it looks silly, no bicycle).”

Physical Changes in Late Adulthood

Is old age “more to be feared than death” (Juvenal, *The Satires*)? Or is life “most delightful when it is on the downward slope” (Seneca, *Epistulae ad*

Lucilium)? What is it like to grow old?



Rick Doyle/Corbis Documentary/Getty Images

Adult abilities vary widely George Blair was, at age 92, the world's oldest barefoot water skier. He is shown here in 2002 when he first set the record, at age 87. (He died in 2013 at age 98.)

Life Expectancy

From 1950 to 2015, life expectancy at birth increased worldwide from 46.5 years to 71 years—and to 80 and beyond in twenty-nine countries (WHO, 2016). What a gift—two decades more of life! In China, the United States, the United Kingdom, Canada, and Australia (to name some countries where students read this book), life expectancy has risen to 76, 79, 81, 82, and 82, respectively (WHO, 2016). This increasing life expectancy (humanity's greatest achievement, say some) combines with decreasing birthrates: Older adults are a growing population segment, creating an increasing demand for hearing aids, retirement villages, and nursing homes. Today, 1 in 10 people worldwide are 60 or older. The United Nations (2015) projects that number will triple to nearly 3 in 10 by 2100 (and to nearly 4 in 10 in Europe).

Throughout the life span, males are more prone to dying. Although 126 male embryos begin life for every 100 females, the sex ratio is down to 105 males for every 100 females at birth (Strickland, 1992). During the first year, male infants' death rates exceed females' by one-fourth. Worldwide, women outlive men by 4.7 years (WHO, 2016). (Rather than marrying a man older than themselves, 20-year-old women who want a husband who shares their life expectancy should wait for the 16-year-old boys to mature.) By age 100, women outnumber men 5 to 1.

But few of us live to 100. Disease strikes. The body ages. Its cells stop reproducing. It becomes frail and vulnerable to tiny insults—hot weather, a fall, a mild infection—that at age 20 would have been trivial. Tips of chromosomes, called *telomeres*, wear down, much as the tip of a shoelace frays. This wear is accelerated by smoking, obesity, or stress. Breast-fed children have longer telomeres, while those who suffer frequent abuse or bullying exhibit the biological scars of shortened telomeres (Shalev et al., 2013). As telomeres shorten, aging cells may die without being replaced with perfect genetic replicas (Epel, 2009).

> “*I intend to live forever—so far, so good.*”
>
> *Comedian Steven Wright*

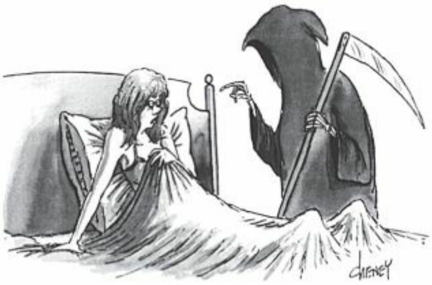
Low stress and good health habits enable longevity, as does a positive spirit. Chronic anger and depression increase our risk of premature death. Researchers have even observed an intriguing *death-deferral* phenomenon (Shimizu & Pelham, 2008). Across one 15-year period, 2000 to 3000 more Americans died on the two days after Christmas than on Christmas and the two days before. The death rate also increases when people reach their birthdays, and when they survive until after other milestones, like the first day of the new millennium.

Pascal Parrot/Getty Images

World record for longevity? French woman Jeanne Calment, the oldest human in history with authenticated age, died in 1998 at age 122. At age 100, she was still riding a bike. At age 114, she became the oldest film actor ever, by portraying herself in *Vincent and Me.*

Sensory Abilities, Strength, and Stamina

Although physical decline begins in early adulthood, we are not usually acutely aware of it until later in life, when the stairs get steeper, the print gets smaller, and other people seem to mumble more. Visual sharpness diminishes, as does distance perception and adaptation to light-level changes. Muscle strength, reaction time, and stamina also diminish, as do smell, hearing, and touch. In Wales, teens' loitering around a convenience store has been discouraged by a device that emits an aversive high-pitched sound that almost no one over 30 can hear (Lyall, 2005).



The New Yorker Collection, 1999 Tom Cheney
from cartoonbank.com

"Happy fortieth. I'll take the muscle tone in your upper arms, the girlish timbre of your voice, your amazing tolerance for caffeine, and your ability to digest french fries. The rest of you can stay."

With age, the eye's pupil shrinks and its lens becomes less transparent, reducing the amount of light reaching the retina. A 65-year-old retina receives only about one-third as much light as its 20-year-old counterpart (Kline & Schieber, 1985). Thus, to see as well as a 20-year-old when reading or driving, a 65-year-old needs three times as much light—a reason for buying cars with untinted windshields. This also explains why older people sometimes ask younger people, "Don't you need better light for reading?"

Health

As people age, they care less about what their bodies look like and more about how their bodies function. For those growing older, there is both bad and good news about health. The bad news: The body's disease-fighting immune system weakens, making older adults more susceptible to life-threatening ailments such as cancer and pneumonia. The good news: Thanks partly to a lifetime's accumulation of antibodies, people over 65 suffer fewer short-term ailments, such as common flu and cold viruses. One study found they were half as likely as 20-year-olds and one-fifth as likely as preschoolers to suffer upper respiratory flu each year (National Center for Health Statistics, 1990).

FYI

Most stairway falls taken by older people occur on the top step, precisely where the person typically descends from a window-lit hallway into the darker stairwell (Fozard & Popkin, 1978). Our knowledge of aging could be used to design environments that would reduce such accidents (National Research Council, 1990).

The Aging Brain

Up to the teen years, we process information with greater and greater speed (Fry & Hale, 1996; Kail, 1991). But compared with you, older people take a bit more time to react, to solve perceptual puzzles, even to remember names (Bashore et al., 1997; Verhaeghen & Salthouse, 1997). At video games, most 70-year-olds are no match for a 20-year-old. This processing lag can also have deadly consequences (Aichele et al., 2016). As **Figure 54.1** indicates, fatal accident rates per mile driven increase sharply after age 75. By age 85, they exceed the 16-year-old level. Older drivers appear to focus well on the road ahead, but attend less to other vehicles approaching from the side (Pollatsek et al., 2012). Nevertheless, because older people drive less, they account for fewer than 10 percent of crashes (Coughlin et al., 2004).

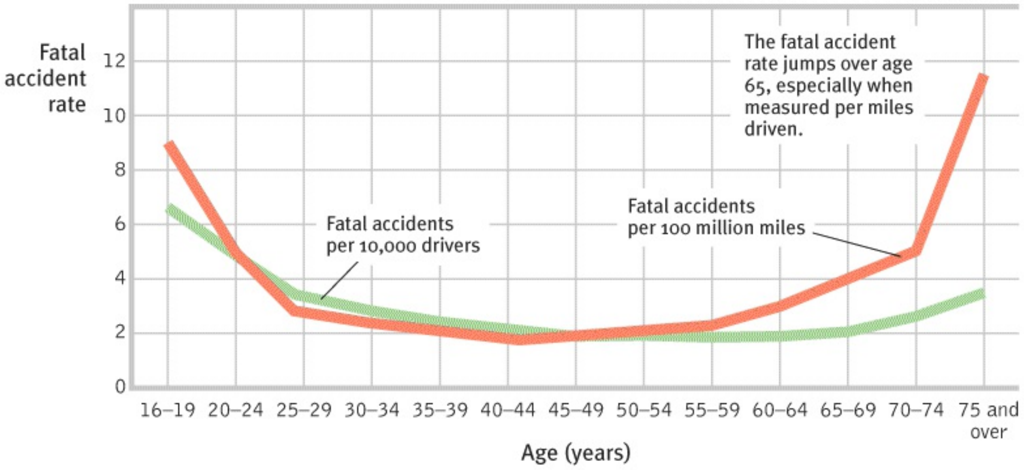


Figure 54.1
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 54.1 Age and driver fatalities

Slowing reactions contribute to increased accident risks among those 75 and older, and their greater fragility increases their risk of death when accidents happen (NHTSA, 2000). Would you favor driver exams based on performance, not age, to screen out those whose slow reactions or sensory impairments indicate accident risk?

Brain regions important to memory begin to atrophy during aging (Fraser et al., 2015; Ritchie et al., 2015). The blood-brain barrier also breaks down beginning in the hippocampus, which furthers cognitive decline (Montagne et al., 2015). No wonder older adults feel older after taking a memory test: It's like "aging 5 years in 5 minutes," joked one research team (Hughes et al., 2013). In early adulthood, a small, gradual net loss of brain cells begins, contributing by age 80 to a brain-weight reduction of 5 percent or so. Earlier, we noted that late-maturing frontal lobes, which help us override our undesirable urges, help account for teen impulsivity. Late in life, some of that impulsiveness often returns as those same frontal lobes begin to atrophy, seemingly explaining older people's occasional blunt questions ("Have you put on weight?") or inappropriate comments (von Hippel, 2007, 2015). But good news: There is still some *plasticity* in the aging brain, which partly compensates for what it loses by recruiting and reorganizing neural networks (Park & McDonough, 2013). During memory tasks, for example, the left frontal lobes are especially active in young adult brains, while older adult brains use both left and right frontal lobes.

Nicole Bengiveno/The New York Times/Redux Pictures

Suiting up for old age A long life is a gift. To reach old age, it takes good genes, a nurturing environment, and a little luck. New technology allows you to put yourself in your elders' shoes. In these special suits, younger people can hear, see, and move as if they were 85 years old.

Exercise and Aging

And more good news: Exercise slows aging, as shown in studies of identical twin pairs in which only one twin exercised (Iso-Markku et al., 2016; Rottensteiner et al., 2015). Active older adults tend to be mentally quick older adults. Physical exercise not only enhances muscles, bones, and energy and helps prevent obesity and heart disease, it maintains the telomeres that protect the chromosome ends and even appears to slow the progression of Alzheimer's disease (Leslie, 2011; Loprinzi et al., 2015; Smith et al., 2014).

Shoot, we'd better hurry up and figure this out.
Streeter
Aging researchers

Betsy Streeter/CartoonStock

Exercise also stimulates brain cell development and neural connections, thanks perhaps to increased oxygen and nutrient flow (Erickson et al., 2013; Fleischman et al., 2015; Pereira et al., 2007). Sedentary older adults randomly assigned to aerobic exercise programs exhibit enhanced memory, sharpened judgment, and reduced risk of severe cognitive decline (Raji et al., 2016; Smith, 2016). In aging brains, exercise reduces brain shrinkage (Gow et al., 2012). It promotes neurogenesis (the birth of new nerve cells) in the hippocampus, a brain region important for memory formation (Erickson, 2009; Pereira et al., 2007). And it increases the cellular mitochondria that help power both muscles and brain cells (Steiner et al., 2011). We are more likely to rust from disuse than to wear out from overuse. Fit bodies support fit minds.

Cognitive Development

Aging and Memory

54-2 How does memory change with age?

Among the most intriguing developmental psychology questions is whether adult cognitive abilities, such as memory, intelligence, and creativity, parallel the gradually accelerating decline of physical abilities.

As we age, we remember some things well. Looking back in later life, adults asked to recall the one or two most important events over the last half-century tend to name events from their teens or twenties (Conway et al., 2005; Rubin et al., 1998). They also display this “reminiscence bump” when asked to name their all-time favorite music, movies, and athletes (Janssen et al., 2012). Whatever people experience around this time—the Vietnam war, the 9/11 terrorist attacks, the election of the first Black U.S. president—becomes pivotal (Pillemer, 1998; Schuman & Scott, 1989). Our teens and twenties hold so many memorable “firsts”—first kiss, first job, first day at college or university, first meeting our romantic partner’s parents.

AP® EXAM TIP

This section is a good example of the complexity of seemingly simple questions. It seems like one should be able to answer a question like “Does memory decline with age?” with a straightforward *yes* or *no*. People are complex. Development is complex. We should not be surprised to learn that many factors influence memory in adulthood.

Early adulthood is indeed a peak time for some types of learning and remembering. In one test of recall, people watched video clips as 14 strangers said their names, using a common format: “Hi, I’m Larry”

(Crook & West, 1990). Then those strangers reappeared and gave additional details. For example, they said, “I’m from Philadelphia,” providing more visual *and* voice cues for remembering the person’s name. As **Figure 54.2** shows, after a second and third replay of the introductions, everyone remembered more names, but younger adults consistently surpassed older adults. How well older people remember depends in part on the task. In another experiment, when asked to *recognize* 24 words they had earlier tried to memorize, older adults showed minimal memory decline. When asked to *recall* that information without clues, however, the decline was greater (**Figure 54.3**).

Data from Schonfield & Robertson, 1966.

Figure 54.3 Recall and recognition in adulthood

In this experiment, the ability to *recall* new information declined during early and middle adulthood, but the ability to *recognize* new information did not.

Teens and young adults surpass both young children and 70-year-olds at *prospective memory* ("Remember to . . .") (Zimmermann & Meier, 2006). But older people's prospective memory remains strong when events help trigger a memory (as when walking by a convenience store triggers "Pick up milk!"). Time-based tasks ("Client meeting at 3:00 P.M.") and especially habitual tasks ("Take medications at 9:00 a.m., 2:00 P.M., and 6:00 P.M.") can be challenging (Einstein & McDaniel, 1990; Einstein et al., 1995, 1998). To minimize such problems, older adults rely more on time management and reminder cues, such as notes to themselves (Henry et al., 2004). This might have helped John Basinger, who, at age 76, memorized all 12 volumes of John Milton's epic poem *Paradise Lost* and became the subject of a psychology journal article (Seamon et al., 2010; Weir, 2010). A local paper scheduled an interview with Basinger, which he forgot to attend. Calling the reporter to apologize, he noted the irony of forgetting his interview about memory!

In our capacity to learn and remember, as in other areas of development, we show individual differences. Younger adults vary in their abilities to learn and remember, but 70-year-olds vary much more. “Differences between the most and least able 70-year-olds become much greater than between the most and least able 50-year-olds,” reported Oxford researcher Patrick Rabbitt (2006). Some 70-year-olds perform below nearly all 20-year-olds; other 70-year-olds match or outdo the average 20-year-old.

> “*I am still learning.*”
>
> *Michelangelo, 1560, at age 85*

No matter how quick or slow we are, remembering seems also to depend on the type of information we are trying to retrieve. If the information is meaningless—nonsense syllables or unimportant events—then the older we are, the more errors we are likely to make. If the information is *meaningful*, as was *Paradise Lost* for John Basinger, older people’s rich web of existing knowledge will help them to hold it. But they may take longer than younger adults to *produce* the words and things they know. Older adults also more often experience tip-of-the-tongue forgetting (Ossher et al., 2012). Quick-thinking game show winners have usually been young or middle-aged adults (Burke & Shafto, 2004).

TRY THIS

What experiences from your high school years do you think you may never forget? (These years, and the next few, will be among the times of your life you may remember most easily when you are 50.)

Maintaining Mental Abilities

Psychologists who study the aging mind debate whether “brain fitness” computer-based training programs can build mental muscles and stave off cognitive decline. Our brain remains plastic throughout life (Gutchess, 2014). So, can exercising our brains on a “cognitive treadmill”—with memory, visual tracking, and problem-solving exercises—avert losing our minds? “At every point in life, the brain’s natural plasticity gives us the ability to improve . . . function,” said one neuroscientist-entrepreneur (Merzenich, 2007). One analysis of cognitive training programs showed that they consistently improved scores on tests related to their training (Simons et al., 2016).

Based on such findings, some computer game makers have been marketing daily brain-exercise programs for older adults. But other researchers, after reviewing all the available studies, advise caution (Melby-Lervåg et al., 2016). One team of experts reported “extensive evidence that brain-training interventions improve performance on the trained tasks, less evidence that such interventions improve performance on closely related tasks, and little evidence that training enhances performance on distantly related tasks or that training improves everyday cognitive performance” (Simons et al., 2016, p. 103). As researcher Zach Hambrick (2014) explains, “Play a video game and you’ll get better at that video game, and maybe at very similar video games”—but not at driving a car or filling out your tax return.

In 2016, the maker of one prominent brain-training program, Lumosity, was fined $2 million for deceiving customers about the program’s supposed benefits. “Lumosity preyed on consumers’ fears about age-related cognitive decline,” said the Federal Trade Commission’s Jessica Rich (FTC, 2016). “But Lumosity simply did not have the science to back up its ads.”

Module 62 explores another dimension of cognitive development: intelligence. As we will see, **cross-sectional studies** (comparing people of different ages) and **longitudinal studies** (restudying the same people over time) have identified mental abilities that do and do not change as people age. Age is less a predictor of memory and intelligence than is proximity to death. Knowing whether someone is 8 months or 8 years from a natural death, regardless of age, gives a clue to that person’s mental ability. In the last three or four years of life and especially as death approaches, negative feelings and cognitive decline typically increase (Vogel et al., 2013; Wilson et al., 2007b). Researchers call this near-death drop *terminal* *decline* (Backman & MacDonald, 2006). Our goals also shift: We’re driven less to learn and more to connect socially (Carstensen, 2011).

cross-sectional study

research that compares people of different ages at the same point in time.

longitudinal study

research that follows and retests the same people over time.

> “*The sudden knowledge of the fragility of his life narrowed his focus and altered his desires.... It made him visit with his grandchildren more often, put in an extra trip to see his family in India, and tamp down new ventures.*”

Neurocognitive Disorders and Alzheimer’s Disease

54-3 How do neurocognitive disorders and Alzheimer’s disease affect cognitive ability?

Most people who live into their nineties do so with clear minds. Some, unfortunately, suffer substantial psychological decline that is *not* normal aging. Among older adults, hearing loss, and its associated social isolation, predicts risk of depression and accelerated mental decline (Lin et al., 2011a,b, 2013; Mick & Pichora-Fuller, 2016). Compared with people with good hearing, those with hearing loss show declines in memory, attention, and learning about three years earlier. A series of small strokes, a brain tumor, or alcohol use disorder can progressively damage the brain, causing that mental erosion we call a **neurocognitive disorder** (**NCD,** formerly called *dementia*). Heavy midlife smoking more than doubles later risk of the disorder (Rusanen et al., 2011). The feared brain ailment **Alzheimer’s disease** strikes 3 percent of the world’s population by age 75. Up to age

95, the incidence of mental disintegration doubles roughly every 5 years.

neurocognitive disorders (NCDs)

acquired (not lifelong) disorders marked by cognitive deficits; often related to Alzheimer’s disease, brain injury or disease, or substance abuse. In older adults, neurocognitive disorders were formerly called *dementia*.

Alzheimer’s disease

a neurocognitive disorder marked by neural plaques, often with onset after age 80, and entailing a progressive decline in memory and other cognitive abilities.

Alzheimer’s destroys even the brightest of minds. First memory deteriorates, then reasoning. (Occasionally forgetting where you laid the car keys is no cause for alarm; forgetting how to get home may suggest Alzheimer’s.) Robert Sayre (1979) recalled his father shouting at his afflicted mother to “think harder,” while his mother, confused, embarrassed, on the verge of tears, randomly searched the house for lost objects. As the disease runs its course, after 5 to 20 years, the person becomes emotionally flat, then disoriented and disinhibited, then incontinent, and finally mentally vacant—a sort of living death, a mere body stripped of its humanity.

Underlying the symptoms of Alzheimer’s are a loss of brain cells and a deterioration of neurons that produce the neurotransmitter acetylcholine, which is vital to memory and thinking. An autopsy reveals two telltale abnormalities in these acetylcholine-producing neurons: shriveled protein filaments in the cell body, and clumps of a free-floating protein fragment that accumulate as plaque at neuron tips where synaptic communication normally occurs. Long before symptoms appear, new technologies can now test for the Alzheimer’s susceptibility gene or check spinal fluid for the culprit protein fragments (De Meyer et al., 2010; Luciano et al., 2009). Such discoveries have stimulated a race to invent and test drugs that may forestall the disease, such as by reducing the activity of a memory-inhibiting neurotransmitter called GABA (Chen et al., 2014). The discovery of 21 associated genes may help (Lambert et al., 2013).

A diminishing sense of smell and slowed or wobbly walking foretell Alzheimer's (Belluck, 2012; Wilson et al., 2007a). In people at risk for Alzheimer's, brain scans (**Figure 54.4**) have also revealed—before symptoms appear—the degeneration of critical brain cells and diminished activity in Alzheimer's-related brain areas (Apostolova et al., 2006; Johnson et al., 2006; Wu & Small, 2006). When people memorized words, scans also showed diffuse brain activity, as if more exertion was required to achieve the same performance (Bookheimer et al., 2000).

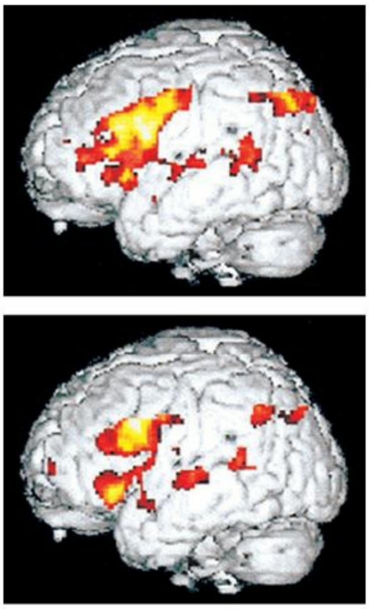

Figure 54.4
Susan Bookheimer

Figure 54.4 Predicting Alzheimer's disease

During a memory test, MRI scans of the brains of people at risk for Alzheimer's (top) revealed more intense activity (yellow, followed by orange and red) when compared with normal brains (bottom). As brain scans and genetic tests make it possible to identify those likely to suffer Alzheimer's, would you want to be tested? At what age?

Alzheimer's is somewhat less common among those who keep their minds and bodies active, through activities like reading, attending educational lectures, and running or lifting weights (Agrigoroaei & Lachman, 2011). As with muscles, so with the brain: Those who use it less often lose it.

Social Development

54-4 What themes and influences mark our social journey from early adulthood to death?

Many differences between younger and older adults are created by significant life events. A new job means new relationships, new expectations, and new demands. Marriage brings the joy of intimacy and the stress of merging two lives. The three years surrounding the birth of a child bring increased life satisfaction for most parents (Dyrdal & Lucas, 2011). The death of a loved one creates an irreplaceable loss. Do these adult life events shape a sequence of life changes?

Adulthood’s Ages and Stages

As people enter their forties, they undergo a transition to middle adulthood, a time when they realize that life will soon be mostly behind instead of ahead of them. Some psychologists have argued that for many the *midlife transition* is a crisis, a time of great struggle, regret, or even feeling struck down by life. The popular image of the midlife crisis—an early-forties man who forsakes his family for a younger romantic partner and a hot sports car—is more a myth than reality. Unhappiness, job dissatisfaction, marital dissatisfaction, divorce, anxiety, and suicide do *not* surge during the early forties (Hunter & Sundel, 1989; Mroczek & Kolarz, 1998). Divorce, for example, is most common among those in their twenties, suicide among those in their seventies and eighties. One study of emotional instability in nearly 10,000 men and women found “not the slightest evidence” that distress peaks anywhere in the midlife age range (McCrae & Costa, 1990).

For the 1 in 4 adults who report experiencing a life crisis, the trigger is not age, but a major event, such as illness, divorce, or job loss (Lachman, 2004). Some middle-aged adults describe themselves as a “sandwich generation,” simultaneously supporting their aging parents and their emerging adult children or grandchildren (Riley & Bowen, 2005).

Life events trigger transitions to new life stages at varying ages. The **social clock**—the definition of "the right time" to leave home, get a job, marry, have children, and retire—varies from era to era and culture to culture. The once-rigid sequence has loosened; the social clock still ticks, but people feel freer about being out of sync with it.

social clock

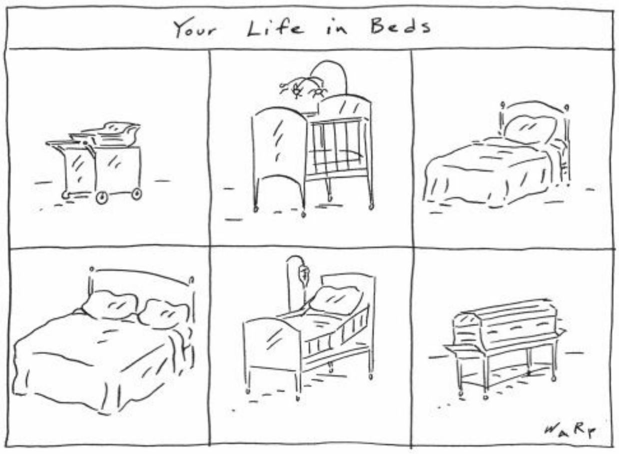
the culturally preferred timing of social events such as marriage, parenthood, and retirement.

> "*The important events of a person's life are the products of chains of highly improbable occurrences.*"
>
> *Joseph Traub, "Traub's Law," 2003*

Even *chance events* can have lasting significance, by deflecting us down one road rather than another. Albert Bandura (1982, 2005) recalls the ironic true story of a book editor who came to one of Bandura's lectures on the "Psychology of Chance Encounters and Life Paths"—and ended up marrying the woman who happened to sit next to him. The sequence that led to my [DM's] authoring this book (which was not my idea) began with my being seated near, and getting to know, a distinguished colleague at an international conference. The road to my [ND's] co-authoring this book began in a similarly unplanned manner: After stumbling on an article about my professional life, DM invited me to visit his college. There, we began a conversation that resulted in our collaboration. Chance events can change our lives.

Adulthood's Commitments

Two basic aspects of our lives dominate adulthood. Erik Erikson called them *intimacy* (forming close relationships) and *generativity* (being productive and supporting future generations). Sigmund Freud (1935/1960) put this more simply: The healthy adult, he said, is one who can *love* and *work.*



The New Yorker Collection, 2006, John Donohue from cartoonbank.com.

Love

Blend Images/Alamy

Love Intimacy, attachment, commitment—love by whatever name—is central to healthy and happy adulthood.

We typically flirt, fall in love, and commit—one person at a time. “Pair-bonding is a trademark of the human animal,” observed anthropologist Helen Fisher (1993). From an evolutionary perspective, relatively monogamous pairing makes sense: Parents who cooperated to nurture their children to maturity were more likely to have their genes passed along to posterity than were parents who didn’t.

Adult bonds of love are most satisfying and enduring when marked by a similarity of interests and values, a sharing of emotional and material support, and intimate self-disclosure (see Module 79). There also appears to be “vow power.” Straight and gay relationships sealed with commitment more often endure (Balsam et al., 2008; Rosenfeld, 2014). Such bonds are especially likely to last when couples marry after age 20 and are well educated. Compared with their counterparts of 30 years ago, people in Western countries *are* better educated and marrying later (Wolfinger, 2015). These trends may help explain why the American divorce rate, which surged from 1960 to 1980, has since leveled off and even slightly declined in some areas (Schoen & Canudas-Romo, 2006). Canadian divorce rates since the 1980s have followed a similar pattern (Statistics Canada, 2011). Despite the drop in divorce, our standards have risen. We now hope not only for an enduring bond, but also for a mate who is a wage earner, caregiver, intimate friend, and warm and responsive lover (Finkel, 2017).

Historically, couples have met at school, on the job, or through friends and family. Thanks to the Internet, many couples now meet online—as have nearly a quarter of heterosexual couples and some two-thirds of same-sex couples in one recent national survey (**Figure 54.5**).

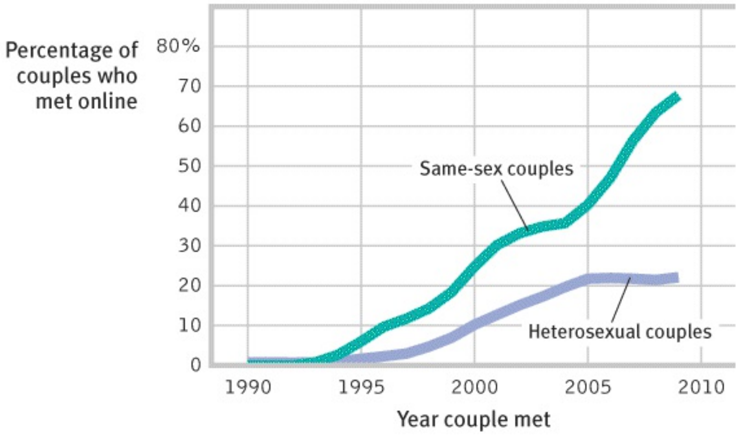

Figure 54.5

Data from Rosenfeld, 2013; Rosenfeld & Thomas, 2012.

Figure 54.5 The changing way Americans meet their partners

A national survey of 2452 straight couples and 462 gay and lesbian couples reveals the increasing role of the Internet.

Might test-driving life together minimize divorce risk? In Europe, Canada, and the United States, those who live together before marriage (and especially before engagement) have had *higher* rates of divorce and marital dysfunction than those who did not (Goodwin et al., 2010; Jose et al., 2010; Manning & Cohen, 2012; Stanley et al., 2010). Three factors contribute. First, those who live together tend to be initially less committed to the ideal of enduring marriage. Second, they may become even less marriage-supporting while living together. Third, it’s more awkward to break up with a cohabiting partner than with a dating partner, leading some cohabiters to marry someone “they otherwise would have left behind” (Stanley & Rhoades, 2016a,b).

Although there is more variety in relationships today, the institution of marriage endures. Ninety-five percent of Americans have either married or want to (Newport & Wilke, 2013). In Western countries, people marry for love. What counts as a “very important” reason to marry? Among Americans, 31 percent say financial stability, and 93 percent say love (Cohn, 2013). And marriage is a predictor of happiness, sexual satisfaction, income, and physical and mental health (Scott et al., 2010). National Opinion Research Center surveys of more than 50,000 heterosexual Americans between 1972 and 2014 reveal that 40 percent of married adults, though only 23 percent of unmarried adults, have reported being “very happy.” Lesbian couples, too, have reported greater well-being than those who are single (Peplau & Fingerhut, 2007; Wayment & Peplau, 1995). Moreover, neighborhoods with high marriage rates typically have low rates of social pathologies such as crime, delinquency, and emotional disorders among children (Myers & Scanzoni, 2005).

TRY THIS

What do you think? Does marriage correlate with happiness because marital support and intimacy breed happiness, because happy people more often marry and stay married, or both?

Relationships that last are not always devoid of conflict. Some couples fight but also shower each other with affection. Other couples never raise their voices yet also seldom praise each other or nuzzle. Both styles can last. After observing the interactions of 2000 couples, John Gottman (1994) reported one indicator of marital success: at least a five-to-one ratio of positive to negative interactions. Stable marriages provide five times more instances of smiling, touching, complimenting, and laughing than of sarcasm, criticism, and insults. So, if you want to predict which couples will stay together, don't pay attention to how passionately they are in love. The pairs who make it are more often those who refrain from putting down their partners. To prevent a cancerous negativity, successful couples learn to fight fair (to state feelings without insulting) and to steer conflict away from chaos with comments like "I know it's not your fault" or "I'll just be quiet for a moment and listen."

> "*Our love for children is so unlike any other human emotion. I fell in love with my babies so quickly and profoundly, almost completely independently of their particular qualities. And yet 20 years later I was (more or less) happy to see them go—I had to be happy to see them go. We are totally devoted to them when they are little and yet the most we can expect in return when they grow up is that they regard us with bemused and tolerant affection.*"
>
> *Developmental psychologist Alison Gopnik, "The Supreme Infant," 2010*

Often, love bears children. For most people, this most enduring of life changes is a happy event—one that adds meaning, joy, and occasional stress (S. K. Nelson et al., 2013; Witters, 2014). "I feel an overwhelming love for my children unlike anything I feel for anyone else," said 93 percent of American mothers in a national survey (Erickson & Aird, 2005). Many fathers feel the same. A few weeks after the birth of my first child, I [DM] was suddenly struck by a realization: "So *this* is how my parents felt about me!"

When children begin to absorb time, money, and emotional energy, satisfaction with the relationship itself may decline (Doss et al., 2009). This is especially likely among employed women who, more than they expected, may also carry the burden of doing more chores at home. Putting effort into creating an equitable relationship can thus pay double dividends: greater satisfaction, which breeds better parent-child relations (Erel & Burman, 1995).

Although love bears children, children eventually leave home. This departure is a significant and sometimes difficult event. But for most people, an empty nest is a happy place (Adelmann et al., 1989; Gorchoff et al., 2008). Many parents experience a "postlaunch honeymoon," especially if they maintain close relationships with their children (White & Edwards, 1990). As Daniel Gilbert (2006) has said, "The only known symptom of 'empty nest syndrome' is increased smiling."

Work

Left: Hill Street Studios/Getty Images; Right: © Jose Luis Pelaez Inc/Blend Images/Corbis

Job satisfaction and life satisfaction Work can provide us with a sense of identity and competence, and opportunities for accomplishment. Perhaps this is why challenging and interesting occupations enhance people's happiness.

For many adults, the answer to "Who are you?" depends a great deal on the answer to "What do you do?" For women and men, choosing a career path is difficult, especially during bad economic times. Even in the best of times, few students in their first two years of college or university can predict their later careers.

FYI

For more on work, including discovering your own strengths, see Module 82, Psychology at Work.

In the end, happiness is about having work that fits your interests and provides you with a sense of competence and accomplishment. It is giving generously of your time and resources (Mogilner & Norton, 2016; Whillans et al., 2016). It is having a close, supportive companion, or family and friends, who notice and cheer your accomplishments (Campos et al., 2015). And for some, it includes having children who love you and whom you love and feel proud of.

Well-Being Across the Life Span

54-5 How does our well-being change across the life span?

To live is to grow older. This moment marks the oldest you have ever been and the youngest you will henceforth be. That means we all can look back with satisfaction or regret, and forward with hope or dread. When asked what they would have done differently if they could relive their lives, people's most common answer has been "taken my education more seriously and worked harder at it" (Kinnier & Metha, 1989; Roese & Summerville, 2005). Other regrets—"I should have told my father I loved him," "I regret that I never went to Europe"—have also focused less on mistakes made than on the things one *failed* to do (Gilovich & Medvec, 1995).

> “*When you were born, you cried and the world rejoiced. Live your life in a manner so that when you die the world cries and you rejoice.*”
>
> *Native American proverb*

From the teens to midlife, people typically experience a strengthening sense of identity, confidence, and self-esteem (Huang, 2010; Robins & Trzesniewski, 2005). In later life, challenges arise: Income shrinks, work opportunities go away, the body deteriorates, recall fades, energy wanes, family members and friends die or move away, and the great enemy, death, looms ever closer. Yet, a study revealed that compared with people who *imagine* what they would feel when facing death, those actually facing a terminal illness and imminent death are more positive and less despairing. In the researchers' words, "Dying is unexpectedly positive" (Goranson et al., 2017)

Moreover, the over-65 years are not notably unhappy. Gallup asked 658,038 people worldwide to rate their lives from 0 ("the worst possible life") to 10 ("the best possible life"). Age—from 15 to over 90 years—gave no clue to life satisfaction (Morrison et al., 2014). Self-esteem remains stable (Wagner et al., 2013). Positive feelings, supported by enhanced emotional control, tend to grow after midlife, and negative feelings subside (Stone et al., 2010; Urry & Gross, 2010). Compared with younger Chinese and American adults, for example, older adults are *more* attentive to positive news (Isaacowitz, 2012; Wang et al., 2015b).

Compared with teens and young adults, older adults do, however, tend to have a smaller social network, with fewer friendships and greater loneliness (Luhmann & Hawkley, 2016; Wagner et al., 2016). Like people of all ages, older adults are happiest when not alone (**Figure 54.6**). Older adults experience fewer problems in their relationships—less attachment anxiety, stress, and anger (Chopik et al., 2013; Fingerman & Charles, 2010; Stone et al., 2010). With age, we become more stable and more accepting (Carstensen et al., 2011; Shallcross et al., 2013).

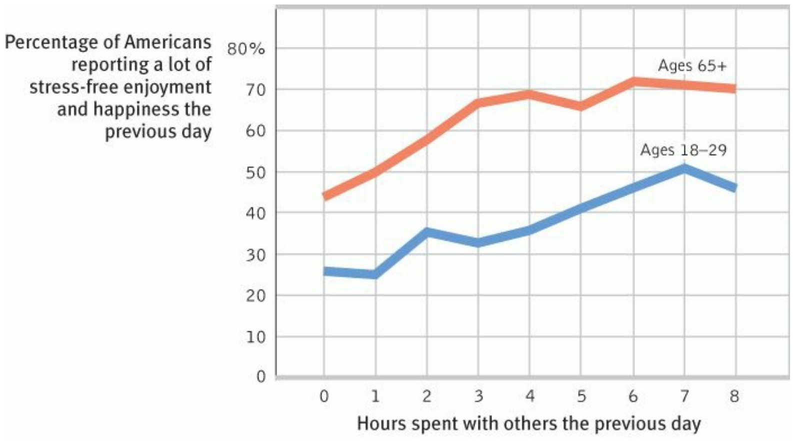

Figure 54.6
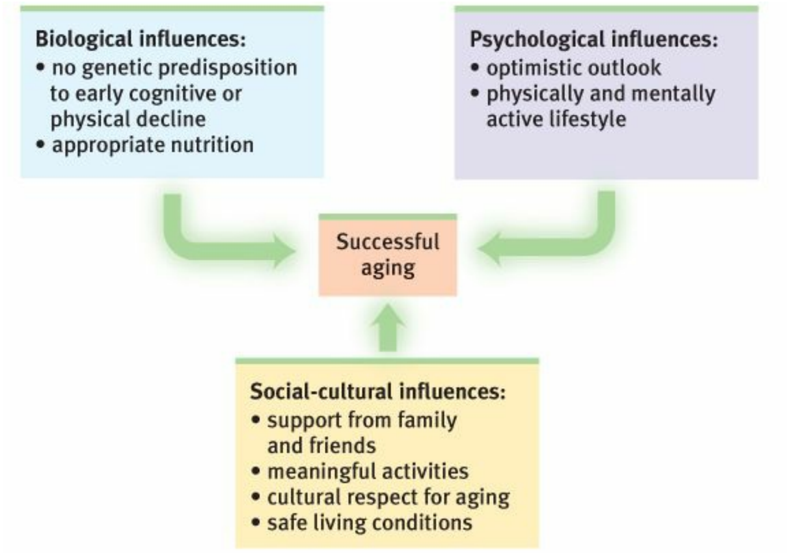
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 54.6 Humans are social creatures

Both younger and older adults report greater happiness when spending time with others. (Note this correlation could also reflect happier people being more social.) (Gallup survey data reported by Crabtree, 2011.)

The aging brain may help nurture these positive feelings. Brain scans of older adults show that the amygdala, a neural processing center for emotions, responds less actively to negative events (but not to positive events) (Mather et al., 2004). Brain-wave reactions to negative images also diminish with age (Kisley et al., 2007). As we reach the later chapters of our lives, our brain enables a contented culmination (Mather, 2016).

Moreover, at all ages, the bad feelings we associate with negative events fade faster than do the good feelings we associate with positive events (Walker et al., 2003). This leaves most older people with the comforting feeling that life, on balance, has been mostly good. Thanks to biological, psychological, and social-cultural influences, more and more people flourish into later life (**Figure 54.7**).



Biological influences:
• no genetic predisposition to early cognitive or physical decline
• appropriate nutrition
Psychological influences:
• optimistic outlook
• physically and mentally active lifestyle
Successful aging
Social-cultural influences:
• support from family and friends
• meaningful activities
• cultural respect for aging
• safe living conditions

Figure 54.7

Figure 54.7 **Biopsychosocial influences on successful aging**

The resilience of well-being across the life span obscures some interesting age-related emotional differences. When researchers mapped people's emotional terrain by periodically signaling them with electronic beepers to report their current activities and feelings, they found that teenagers typically come down from elation or up from gloom in less than an hour, but that adult moods are less extreme and more enduring (Csikszentmihalyi & Larson, 1984). As the years go by, feelings mellow (Brose et al., 2015). Highs become less high, lows less low. Compliments provoke less elation and criticisms less despair, as both become merely additional feedback atop a mountain of accumulated praise and blame. As we age, life therefore becomes less of an emotional roller coaster.

> “*At 20 we worry about what others think of us. At 40 we don’t care what others think of us. At 60 we discover they haven’t been thinking about us at all.*”
>
> *Anonymous*

> “*The best thing about being 100 is no peer pressure.*”
>
> *Lewis W. Kuester, 2005, on turning 100*

Death and Dying

54-6 A loved one’s death triggers what range of reactions?

Warning: If you begin reading the next paragraph, you will die.

> “*Love—why, I’ll tell you what love is: It’s you at 75 and her at 71, each of you listening for the other’s step in the next room, each afraid that a sudden silence, a sudden cry, could mean a lifetime’s talk is over.*”
>
> *Brian Moore,* The Luck of Ginger Coffey, *1960*

But of course, if you hadn’t read this, you would still die in due time. “Time is a great teacher,” noted the nineteenth-century composer Hector Berlioz, “but unfortunately it kills all its pupils.” Death is our inevitable end. We enter the world with a wail, and usually leave it in silence.

Most of us will also cope with the deaths of relatives and friends. For most people, the most difficult separation they will experience is the death of a partner—a loss suffered by four times more women than men.

Maintaining everyday engagements and relationships increases resilience in the face of such a loss (Infurna & Luthar, 2016). But for some, grief is severe, especially when a loved one’s death comes suddenly and before its expected time on the social clock. I [ND] experienced this firsthand when a tragic accident claimed the life of my 60-year-old mother. Such tragedies may trigger a year or more of memory-laden mourning that eventually subsides to a mild depression (Lehman et al., 1987).

For some, the loss is unbearable. One Danish long-term study of more than 1 million people found that about 17,000 of them had suffered the death of a child under 18. In the 5 years following that death, 3 percent of them had a first psychiatric hospitalization, a 67 percent higher rate than among other parents (Li et al., 2005).

Reactions to a loved one’s death range more widely than most suppose. Some cultures encourage public weeping and wailing; others hide grief. Within any culture, individuals differ. Given similar losses, some people grieve hard and long, others less so (Ott et al., 2007). Contrary to popular misconceptions, however:

- Terminally ill and bereaved people do not go through identical predictable stages, such as denial before anger (Friedman & James, 2008; Nolen-Hoeksema & Larson, 1999).
- Those who express the strongest grief immediately do not purge their grief more quickly (Bonanno & Kaltman, 1999; Wortman & Silver, 1989). But grieving parents who try to protect their partner by “staying strong” and not discussing their child’s death may actually prolong the grieving (Stroebe et al., 2013).
- Bereavement therapy and self-help groups offer support, but there is similar healing power in the passing of time, the support of friends, and the act of giving support and help to others (Baddeley & Singer, 2009; Brown et al., 2008; Neimeyer & Currier, 2009). Grieving spouses who talk often with others or receive grief counseling adjust about as well as those who grieve more privately (Bonanno, 2004; Stroebe et al., 2005).

> “*Consider, friend, as you pass by, as you are now, so once was I. As I am now, you too shall be. Prepare, therefore, to follow me.*”
>
> *Scottish tombstone epitaph*

Facing death with dignity and openness helps people complete the life cycle with a sense of life’s meaningfulness and unity—the sense that their existence has been good and that life and death are parts of an ongoing cycle. Although death may be unwelcome, life itself can be affirmed even at death. This is especially so for people who review their lives not with despair but with what Erik Erikson called a sense of *integrity*—a feeling that one’s life has been meaningful and worthwhile.

✓ Check Your Understanding

Ask Yourself

- In what ways are you looking forward to adulthood? What concerns do you have about your own transition into adulthood, and how do you think you might address them?

Test Yourself

- Freud defined the healthy adult as one who is able to ________________ and to ________________.
- What are some of the most significant challenges and rewards of growing old?
- Research has shown that living together before marriage predicts an increased likelihood of future divorce. What are some possible explanations for this correlation?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 54 REVIEW

54-1 What physical changes occur during middle and late adulthood?

- Muscular strength, reaction time, sensory abilities, and cardiac output begin to decline in the mid-twenties and continue to decline throughout middle and late adulthood.
- Women's period of fertility ends with *menopause* around age 50. Men experience a more gradual decline in fertility and sexual response.
- In late adulthood, the immune system weakens, increasing susceptibility to life-threatening illnesses.
- Chromosome tips (telomeres) wear down, reducing the chances of normal genetic replication.
- But for some, longevity-supporting genes, low stress, and good health habits enable better health in later life.

54-2 How does memory change with age?

- As the years pass, recall begins to decline, especially for meaningless information, but recognition memory remains strong.
- Developmental researchers study age-related changes (such as memory) with *cross-sectional studies* (comparing people of different ages) and *longitudinal studies* (retesting the same people over a period of years).
- "Terminal decline" describes the cognitive decline in the final few years of life.

54-3 How do neurocognitive disorders and Alzheimer's disease affect cognitive ability?

- Neurocognitive disorders (NCDs), formerly called *dementia* in older adults, are marked by cognitive deficits.

- Alzheimer’s disease causes the deterioration of memory, then reasoning. After 5 to 20 years, the person becomes emotionally flat, disoriented, disinhibited, incontinent, and finally mentally vacant.

54-4 What themes and influences mark our social journey from early adulthood to death?

- Adults do not progress through an orderly sequence of age-related social stages. Chance events can determine life choices.
- Evidence does not indicate that adults experience a “midlife crisis” or that distress peaks in midlife.
- The *social clock* is a culture’s preferred timing for social events, such as marriage, parenthood, and retirement.
- Adulthood’s dominant themes are love and work, which Erikson called intimacy and generativity.

54-5 How does our well-being change across the life span?

- Our self-confidence and sense of identity tends to strengthen across the life span.
- Surveys show that life satisfaction is unrelated to age. Positive emotions increase after midlife and negative ones decrease.
- As we age, we experience fewer extremes of emotion and mood.

54-6 A loved one’s death triggers what range of reactions?

- People do not grieve in predictable stages, as was once supposed.
- Strong expressions of emotion may not purge grief, and bereavement therapy is not significantly more effective than grieving without such aid.
- Erikson viewed the late-adulthood psychosocial task as developing a sense of integrity (versus despair).

Multiple-Choice Questions

1. Which of the following changes does *not* occur with age?

a. Visual sharpness diminishes.
b. Distance perception is less acute.
c. Adaptation to light-level changes is less rapid.
d. The lens of the eye becomes more transparent.
e. Senses of smell and hearing diminish.

2. As telomeres shorten, aging cells may die without being replaced with perfect genetic replicas. This process is slowed by

a. smoking.
b. obesity.
c. stress.
d. aging.
e. exercise.

3. Olivia and Jackson plan to get married next year. This significant life event will allow them to achieve Erikson's stage of

a. competence.
b. generativity.
c. intimacy.
d. identity.
e. integrity.

4. Brain scans of older adults show that the _________, a neural processing center for emotions, responds less actively to negative events (but not to positive events), and it interacts less with the hippocampus, a brain memory-processing center.

a. amygdala
b. hypothalamus
c. pineal gland
d. thyroid gland
e. thalamus

5. Which of the following is true of menopause?

a. Both men and women experience menopause around the age of 50.
b. Men experience menopause around 50 years of age, but women experience menopause around 65 years of age.
c. Women experience menopause around 50 years of age, but men experience menopause around 65 years of age.
d. Women experience menopause around the age of 50, but men don’t experience menopause.
e. Men experience menopause around the age of 65, but women don’t experience menopause.

6. Which of the following would be considered an example of Erikson’s concept of integrity?

a. A 25-year-old meets and marries the love of his life.
b. A 35-year-old earns a lot of money, though she doesn’t particularly enjoy her job.
c. An 85-year-old looks back at a life well-lived and feels satisfied.
d. A 40-year-old takes pride in her work and how she is raising her children.
e. A 20-year-old decides to become a physician.

Practice FRQs

1. Describe two ways in which cognitive ability declines during adulthood. Name one factor that can slow the decline.

Answer

1 point: There is a decline in recall—the ability to remember factual information—over the course of adulthood. Pages 561–562

1 point: There is a decline in speed of processing, such as the solving of a novel problem or reaction time, over the adult years. Pages 561–562

1 point: Exercise can help reduce cognitive decline. Page 561

2. Numerous biological, psychological, and social-cultural factors affect the way we age. Explain one example for each of the three that contributes to successful aging.

AP® EXAM PRACTICE QUESTIONS

Multiple-Choice Questions

1. What aspect of development did Jean Piaget's theory focus on?

a. Social
b. Moral
c. Cognitive

d. Physical
e. Ego

2. Jayden, age 15, is struggling with how his political views fit with those of his peers and his parents as he moves toward developing what Erikson would call his sense of

a. trust.
b. worth.
c. autonomy.
d. initiative.
e. identity.

3. What is the correct term for a period of time when certain events must take place in order to facilitate proper development?

a. Conservation stage
b. Preoperational stage
c. Attachment period
d. Critical period
e. Assimilation step

4. Which of the following statements about the impact of aging is *true?*

a. During old age, many of the brain's neurons die.
b. If we live to be 90 or older, most of us will eventually become senile.
c. Older people become less susceptible to short-term illnesses.
d. Recognition memory—the ability to identify things previously experienced—declines with age.
e. Life satisfaction peaks in the 50s and then gradually declines after age 65.

5. Kaylee contributes to the flood relief fund because others are doing so, and she doesn't want to look selfish. Kohlberg might explain that she is in the

a. postconventional stage.

b. preconventional stage.
c. conventional stage.
d. preoperational stage.
e. formal operational stage.

6. Mary Ainsworth's research on attachment suggests that a child is most likely to become "securely attached" when exposed to

a. a terry cloth-wrapped "surrogate" mother.
b. a caregiver with the right temperament.
c. consistent, responsive caregivers.
d. an imprinting experience shortly after birth.
e. enriched motor development experiences.

7. Temperament refers to what aspect of an infant's development?

a. Susceptibility to infection and disease
b. Emotional reactivity
c. General intelligence
d. Level of optimism
e. Ability to learn from situations

8. Which of these statements about intelligence and aging is true?

a. Older adults surpass younger adults at recalling information.
b. Older adults outperform teens at prospective memory.
c. There is less variability among 70-year-olds than among 20-year-olds in capacity to learn and remember.
d. When asked to recognize words, older adults show little memory decline.
e. Older adults are less likely than younger adults to make mistakes when remembering meaningless information.

9. Once a sperm penetrates the cell wall of an egg and fertilizes it, this structure is known as what?

a. An embryo
b. A fetus

c. Placenta
d. A teratogen
e. A zygote

0. Peyton is 11 years old and knows 10-7=3 and 3+7=10 but finds it difficult to solve a math problem, such as 3x-5, because she cannot understand why there is a letter in the problem. Piaget would most likely place her in the

a. concrete operational stage.
b. formal operational stage.
c. preoperational stage.
d. sensorimotor stage.
e. preconventional stage.

1. Most adolescents can ponder and debate human nature, good and evil, and truth and justice. According to Piaget, this thinking ability is due to the emergence of which stage?

a. Concrete operational
b. Sensorimotor
c. Preoperational
d. Formal operational
e. Accommodation

2. Mason retired at age 50 and was called “lucky” by his peers. This is because age 65 is the normal retirement age according to the

a. theory of mind.
b. midlife crisis.
c. critical period.
d. life span.
e. social clock.

3. The more often the stimulus is presented, the weaker the response becomes. What do developmental researchers call this decrease in response intensity due to repeated stimulation?

a. Stagnation
b. Attachment
c. Autonomy
d. Imprinting
e. Habituation

4. Ellie and Ella's parents set clear rules, but also have discussions with their daughters about the types of rules and what the consequences should be for breaking the rules. Their parents are evidently following the

a. authoritarian parenting style.
b. research of Harlow.
c. research of Bandura.
d. authoritative parenting style.
e. permissive parenting style.

5. Which of these is an example of a cross-sectional study?

a. The depth perception of infants is measured once a month for six months in a row, starting at age 6 months.
b. Researchers compare the reaction time of 20 sixth graders.
c. The memory of one group of 50-year-olds is measured and compared to a different group of 70-year-olds.
d. A psychologist develops a case study of a woman who is 102 by interviewing her twice a week for 12 weeks.
e. Researchers compare curiosity ratings of a group of toddlers with that same group's SAT scores 15 years later.

6. By providing increasingly difficult words for his second grader to spell, Logan is making use of

a. scaffolding.
b. assimilation.
c. accommodation.
d. imprinting.
e. maturation.

7. Ryan has a difficult time understanding his mother's facial expressions and engages in repetitive actions. One explanation of this is that Ryan is suffering from

a. FAS.
b. ASD.
c. NCD.
d. Metacognition.
e. menopause.

8. Researchers probing the brain in search of explanations for sexual orientation have found differences between homosexual men and heterosexual men in the region known as the

a. hippocampus.
b. amygdala.
c. frontal lobe.
d. medulla.
e. hypothalamus.

9. When she was 45, Sophie decided to go to nursing school because she felt that her corporate job was not fulfilling. Erikson would argue that her career change was an attempt to find a sense of

a. integrity.
b. intimacy.
c. generativity.
d. identity.
e. competence.

0. Studies indicating that self-esteem ratings fall during the early to mid-teen years find that

a. self-image rebounds in the late teens and twenties.
b. self-image does not rebound until age 30.
c. self-image rebounds in males by age 20 but not until age 30 for females.
d. males have higher rates of depression as teens.

e. females continue to have low self-image scores until age 40.

Free-Response Questions

1. Adolescence has been called a time of “storm and stress.” Describe how each of the following might contribute to this storm and stress.

- Limbic system activity
- Frontal lobe development
- Formal operational abilities
- Erikson’s identity versus role confusion stage
- Early physical maturation for girls

Rubric for Free Response Question 1

1 point: The limbic system is primed by surges of hormones at puberty, which may lead some adolescents to seek excitement and, possibly, behave impulsively. Page 534

1 point: The frontal lobes, which are necessary for judgment and planning, continue to develop during adolescence and into the early twenties. Unused pathways are pruned, and increasingly myelinated neurons speed the connection between the frontal lobes and other areas of the brain. Without completed frontal lobe development, adolescents are often unable to exert adult impulse control. They may be more likely to indulge in risky behaviors despite understanding the possible consequences. Page 534

1 point: When adolescents reach the formal operational stage, they have all of the cognitive abilities of earlier stages and can also think abstractly and hypothetically. With the ability to compare reality with a hypothetical ideal, adolescents may be disappointed in what exists, may detect hypocrisy, or may argue with those around them about how to achieve a more just world. Pages 502, 535

1 point: During Erikson’s identity versus role confusion stage, teenagers seek a sense of identity. Adolescents typically try out different versions of “self” before adopting a comfortable identity. This process can be difficult and can lead to conflicts with friends and family. Pages 539–540

1 point: Early maturation puts some girls out of sync with their emotional development and friends’ experiences. They may begin associating with older teens or endure teasing or sexual harassment. Page 534

2. Piaget, Erikson, and Kohlberg described several cognitive, social, and moral reasoning stages of adolescence. Explain each of the following stages.

- Concrete operational
- Formal operational
- Identity versus role confusion
- Intimacy versus isolation
- Conventional level
- Postconventional level

(6 points)

3. Cruz and Eva have a 7-year-old son. He is in the second grade and is extremely obedient. He has many friends, most of whom are on a baseball team with him.

What advice might each of the researchers give to Cruz and Eva about their son’s development?

- Jean Piaget (cognitive development)
- Harry and Margaret Harlow (attachment)
- Lawrence Kohlberg (levels of moral thinking)
- Erik Erikson (psychosocial development)
- Diana Baumrind (parenting styles)

(5 points)

56 Humanistic Theories

57 Trait Theories

58 Social-Cognitive Theories

59 Exploring the Self

Lady Gaga dazzles millions with her unique musical arrangements, tantalizing outfits, and provocative performances. In shows worldwide, Lady Gaga’s most predictable feature is her unpredictability. She has worn a meat dress to an award show, sported 16-inch heels to meet with U.S. President Barack Obama (who later described the interaction as “a little intimidating”), and inspired Super Bowl viewers with her halftime musical performance.

Yet even unpredictable Lady Gaga exhibits distinctive and enduring ways of thinking, feeling, and behaving. Her fans and critics alike can depend on her openness to new experiences and the energy she gets from the spotlight. And they can also rely on her painstaking dedication to her music and performances. She describes her high school self as “very dedicated, very studious, and very disciplined.” Now, in adulthood, she shows similar self-discipline: “I’m very detailed—every minute of the show has got to be perfect.” This unit focuses on the ways we all demonstrate unique and persistent patterns of thinking, feeling, and behaving—our *personality.*

Much of this book deals with personality. Other units consider biological influences on personality; personality development across the life span; how personality relates to learning, motivation, emotion, and health; social influences on personality, and disorders of personality. This unit focuses on personality itself—what it is and how researchers study it.

We begin with two historically important theories of personality that have become part of Western culture: Sigmund Freud’s *psychoanalytic theory* and the *humanistic* approach. These sweeping perspectives on human nature laid the foundation for later personality theorists and for what this unit presents next: newer scientific explorations of personality.

Today’s personality researchers study the basic dimensions of personality, and the interaction of persons and environments. They also study self-esteem, self-serving bias, and cultural influences on our concept of self—that sense of “Who I am.” And they study the unconscious mind—with findings that probably would have surprised even Freud.

▶ **Unit X Overview Video**

Module 55 Psychoanalytic and Psychodynamic Theories

LEARNING TARGETS

- 55-1 Explain what psychologists mean by *personality*, and identity the theories that inform our understanding of personality.
- 55-2 Explain how Sigmund Freud's treatment of psychological disorders led to his view of the unconscious mind, and describe his view of personality.
- 55-3 Identify the developmental stages Freud proposed, and discuss how he thought people defended themselves against anxiety.
- 55-4 Identify which of Freud's ideas his followers accepted and rejected.
- 55-5 Describe *projective tests* and how they are used, and discuss some criticisms of them.
- 55-6 Discuss how contemporary psychologists view Freud's psychoanalysis, and describe how modern research has developed our understanding of the unconscious.

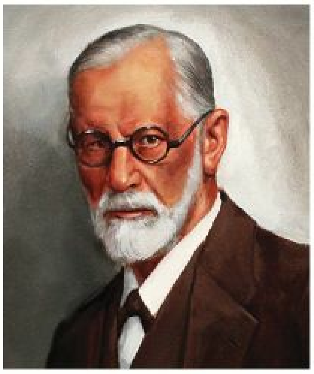
What Is Personality?

55-1 What is *personality*, and what theories inform our understanding of personality?

Psychologists have varied ways to view and study **personality**—our characteristic pattern of thinking, feeling, and acting. Sigmund Freud's *psychoanalytic theory* proposed that childhood sexuality and unconscious motivations influence personality. The *humanistic theories* focused on our inner capacities for growth and self-fulfillment. Later theorists built upon these two broad perspectives. *Trait theories* examine characteristic patterns of behavior *(traits*). *Social-cognitive theories* explore the interaction between people's traits (including their thinking) and their social context. Let's begin with psychodynamic theories.

Personality

an individual's characteristic pattern of thinking, feeling, and acting.



Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Sigmund Freud (1856–1939) "I was the only worker in a new field."

Psychodynamic Theories

Psychodynamic theories of personality view human behavior as a dynamic interaction between the conscious mind and unconscious mind, including associated motives and conflicts. These theories are descended from Freud's **psychoanalysis**—his theory of personality and the associated treatment techniques. Freud's work is so famous that you may assume it's psychology's most important theory. It's not (other theories have more scientific support). However, Freud's focus on our unconscious mind has been followed by today's scientific studies of unconscious information processing.

psychodynamic theories

theories that view personality with a focus on the unconscious and the importance of childhood experiences.

psychoanalysis

Freud's theory of personality that attributes thoughts and actions to unconscious motives and conflicts; the techniques used in treating psychological disorders by seeking to expose and interpret unconscious tensions.

Freud's Psychoanalytic Perspective: Exploring the Unconscious

55-2 How did Sigmund Freud's treatment of psychological disorders lead to his view of the unconscious mind, and what was his view of personality?

Ask 100 people on the street to name a notable deceased psychologist, suggested Keith Stanovich (1996, p. 1), and "Freud would be the winner hands down." In the popular mind, he is to psychology what Elvis Presley is to rock music. Freud's influence lingers not only in psychiatry and clinical psychology, but also in literary and film interpretation. Freud's early twentieth-century concepts penetrate our twenty-first-century language. Without realizing their source, we may speak of *ego, repression, projection, complex* (as in "inferiority complex") *sibling rivalry, Freudian slips,* and *fixation.* So, who was Freud, and what did he teach?

Like all of us, Sigmund Freud was a product of his times. His late 1800s Victorian era was a time of tremendous discovery and scientific advancement, but also of sexual suppression and male dominance. Men's and women's roles were clearly defined, with male superiority assumed and only male sexuality generally acknowledged (discreetly). These assumptions influenced Freud's thinking about personality. He believed that psychological troubles resulted from men's and women's unresolved conflicts with their expected roles.

Long before entering the University of Vienna in 1873, young Freud showed signs of independence and brilliance. He so loved reading plays, poetry, and philosophy that he once ran up a bookstore debt beyond his means. As a teen, he often took his evening meal in his tiny bedroom in order to lose no time from his studies. After medical school he set up a private practice specializing in nervous disorders. Before long, however, he faced patients whose disorders made no neurological sense. A patient might have lost all feeling in a hand—yet there was no sensory nerve that, if damaged, would numb the entire hand and nothing else. Freud's search for a cause for such disorders set his mind running in a direction destined to change human self-understanding.

Do some neurological disorders have psychological causes? Freud's case studies led to his "discovery" of the **unconscious**. He speculated that lost feeling in one's hand might be caused by a fear of touching one's genitals; that unexplained blindness or deafness might be caused by not wanting to see or hear something that aroused intense anxiety. After some early unsuccessful trials with hypnosis, Freud turned to **free association**, in which he told the patient to relax and say whatever came to mind, no matter how embarrassing or trivial. He assumed that a line of mental dominoes had fallen from his patients' distant past to their troubled present. Free association, he believed, would allow him to retrace that line, following a chain of thought leading into the patient's unconscious. There, painful unconscious memories, often from childhood, could be retrieved, reviewed, and released.

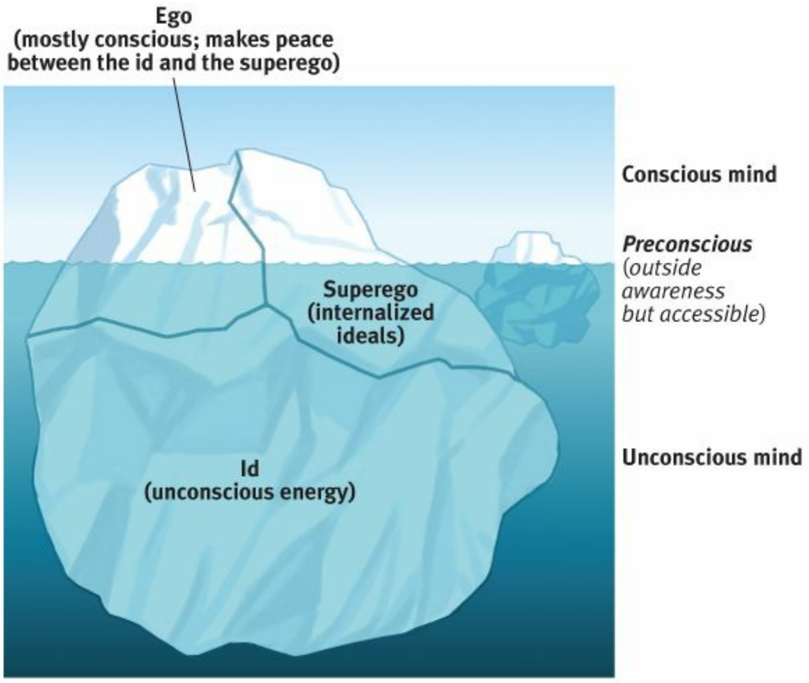
unconscious

according to Freud, a reservoir of mostly unacceptable thoughts, wishes, feelings, and memories. According to contemporary psychologists, information processing of which we are unaware.

free association

in psychoanalysis, a method of exploring the unconscious in which the person relaxes and says whatever comes to mind, no matter how trivial or embarrassing.

Basic to Freud’s theory was his belief that the mind is mostly hidden (**Figure 55.1**). Our *conscious* awareness is like the part of an iceberg that floats above the surface. Beneath this awareness is the larger *unconscious* mind, with its thoughts, wishes, feelings, and memories. Some of these thoughts we store temporarily in a *preconscious* area, from which we can retrieve them into conscious awareness. Of greater interest to Freud was the mass of unacceptable passions and thoughts that he believed we *repress*, or forcibly block from our consciousness because they would be too unsettling to acknowledge. Freud believed that without our awareness, these troublesome feelings and ideas powerfully influence us, sometimes gaining expression in disguised forms—the work we choose, the beliefs we hold, our daily habits, our upsetting symptoms.



Ego
(mostly conscious; makes peace between the id and the superego)
Conscious mind
Preconscious
(outside awareness but accessible)
Superego
(internalized ideals)
Id
(unconscious energy)
Unconscious mind

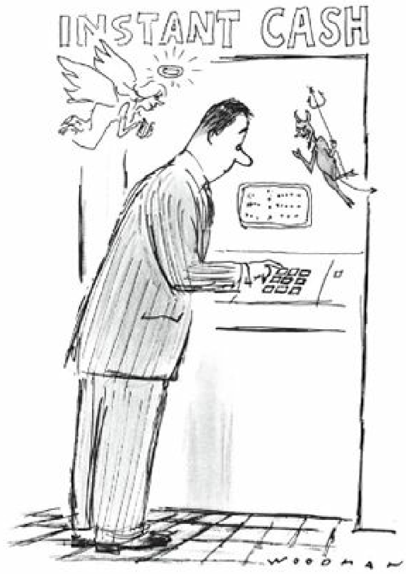
Figure 55.1 Freud's idea of the mind's structure

Psychologists have used an iceberg image to illustrate Freud's idea that the mind is mostly hidden beneath the conscious surface. Note that the id is totally unconscious, but ego and superego operate both consciously and unconsciously. Unlike the parts of a frozen iceberg, however, the id, ego, and superego interact.

AP® EXAM TIP

Be careful: It's easy to confuse Freud's three layers of the mind (conscious, preconscious, and unconscious) with the three parts of personality (the impulsive id, conscious ego, and restraining superego).



Bill Woodman The New Yorker Collection
/The Cartoon Bank

“Fifty is plenty.” “Hundred and fifty.”

The ego struggles to reconcile the demands of superego and id, said Freud.

Personality Structure

Freud believed that human personality, including its emotions and desires, arises from a conflict between impulse and restraint—between our aggressive, pleasure-seeking biological urges and our internalized social controls over these urges. Freud believed personality arises from our efforts to resolve this basic conflict—to express these impulses in ways that bring satisfaction without also bringing guilt or punishment. To understand the mind’s dynamics during this conflict, Freud proposed three interacting systems: the *id*, *ego*, and *superego* (Figure 55.1).

The **id’s** unconscious psychic energy constantly strives to satisfy basic drives to survive, reproduce, and aggress. The id operates on the *pleasure principle:* It seeks immediate gratification. To understand the id’s power, think of a newborn infant crying out for satisfaction, caring nothing for the outside world’s conditions and demands. Or think of people with a present rather than future time perspective—those predisposed to abuse tobacco, alcohol, or other drugs, who would rather party now than sacrifice today’s temporary pleasure for future success and happiness (Fernie et al., 2013; Friedel et al., 2014; Keough et al., 1999).

id

a reservoir of unconscious psychic energy that, according to Freud, strives to satisfy basic sexual and aggressive drives. The id operates on the *pleasure principle*, demanding immediate gratification.

As the **ego** develops, the young child responds to the real world. The ego, operating on the *reality principle*, seeks to gratify the id's impulses in realistic ways that will bring long-term pleasure. (Imagine what would happen if, lacking an ego, we acted on our unrestrained sexual or aggressive impulses.) The ego contains our partly conscious perceptions, thoughts, judgments, and memories.

ego

the largely conscious, "executive" part of personality that, according to Freud, mediates among the demands of the id, superego, and reality. The ego operates on the *reality principle*, satisfying the id's desires in ways that will realistically bring pleasure rather than pain.

Around age 4 or 5, Freud theorized, a child's ego recognizes the demands of the newly emerging **superego**, the voice of our moral compass (conscience) that forces the ego to consider not only the real but also the *ideal*. The superego focuses on how we *ought* to behave. It strives for perfection, judging actions and producing positive feelings of pride or negative feelings of guilt. Someone with an exceptionally strong superego may be virtuous yet guilt ridden; another with a weak superego may be outrageously self-indulgent and remorseless.

superego

the part of personality that, according to Freud, represents internalized ideals and provides standards for judgment (the conscience) and for future aspirations.

Because the superego's demands often oppose the id's, the ego struggles to reconcile the two. The ego is the personality "executive," mediating among the impulsive demands of the id, the restraining demands of the superego, and the real-life demands of the external world. If chaste Conner feels sexually attracted to Tatiana, his ego may satisfy both his id and superego by joining a volunteer organization that Tatiana attends regularly.

Personality Development

55-3 What developmental stages did Freud propose, and how did he think people defended themselves against anxiety?

Analysis of his patients' histories convinced Freud that personality forms during life's first few years. He concluded that children pass through a series of **psychosexual stages**, during which the id's pleasure-seeking energies focus on distinct pleasure-sensitive areas of the body called *erogenous zones* (**Table 55.1**). Each stage offers its own challenges, which Freud saw as conflicting tendencies.

FYI

Erogenous comes from the Greek "eros" (sexual desire) + "genous" (producing); pronounced eh-ROJ-uh-nuss.

psychosexual stages

the childhood stages of development (oral, anal, phallic, latency, genital) during which, according to Freud, the id's pleasure-seeking energies focus on distinct erogenous zones.

TABLE 55.1 Freud's Psychosexual Stages

Stage	Focus

Oral (0–18 months)	Pleasure centers on the mouth—sucking, biting, chewing
Anal (18–36 months)	Pleasure focuses on bowel and bladder elimination; coping with demands for control
Phallic (3–6 years)	Pleasure zone is the genitals; coping with incestuous sexual feelings
Latency (6 to puberty)	A phase of dormant sexual feelings
Genital (puberty on)	Maturation of sexual interests

Freud believed that during the *phallic stage,* for example, boys develop both unconscious sexual desires for their mother and jealousy and hatred for their father, whom they consider a rival. These feelings, he thought, lead boys to feel guilty and to fear punishment, perhaps by castration, from their father. Such was Freud’s (1897) own experience: “I found [myself . . .] in love with my mother and jealous of my father, and I now consider it a universal event in early childhood.” He called this collection of feelings the **Oedipus complex** after the Greek legend of Oedipus, who unknowingly killed his father and married his mother. Some psychoanalysts in Freud’s era believed that girls experience a parallel *Electra complex* (named after a mythological plotting daughter).

Oedipus [ED-uh-puss] complex

according to Freud, a boy’s sexual desires toward his mother and feelings of jealousy and hatred for the rival father.

Children eventually cope with the threatening feelings, said Freud, by repressing them and by identifying with (trying to become like) the rival parent. It’s as though something inside the child decides, “If you can’t beat ’em [the same-sex parent], join ’em.” Through this **identification** process, children’s superegos gain strength as they incorporate many of their parents' values. Freud believed that identification with the same-sex parent provided what psychologists now call our *gender identity*—our sense of being male, female, or some combination of the two. Freud presumed that our early childhood relations—especially with our parents and other caregivers—influence our developing identity, personality, and frailties.

identification

the process by which, according to Freud, children incorporate their parents' values into their developing superegos.

In Freud's view, conflicts unresolved during earlier psychosexual stages could surface as maladaptive behavior in the adult years. At any point in the oral, anal, or phallic stages, strong conflict could lock, or **fixate**, the person's pleasure-seeking energies in that stage. A person who had been either orally overindulged or deprived (perhaps by abrupt, early weaning) might fixate at the oral stage. This orally fixated adult could exhibit either passive dependence (like that of a nursing infant) or an exaggerated denial of this dependence (by acting tough or uttering biting sarcasm). Or the person might continue to seek oral gratification by smoking or excessive eating. In such ways, Freud suggested, the twig of personality is bent at an early age.

fixation

in psychoanalytic theory, according to Freud, a lingering focus of pleasure-seeking energies at an earlier psychosexual stage, in which conflicts were unresolved.

Charles Saxon The New Yorker Collection
/The Cartoon Bank

“Oh for goodness’ sake, smoke!”

Defense Mechanisms

Anxiety, said Freud, is the price we pay for civilization. As members of social groups, we must control our sexual and aggressive impulses, not act them out. But sometimes the ego fears losing control of this inner id–superego war. The presumed result is a dark cloud of unfocused anxiety that leaves us feeling unsettled but unsure why.

Freud proposed that the ego protects itself with **defense mechanisms**—tactics that reduce or redirect anxiety by distorting reality (**Table 55.2**). For Freud, *all defense mechanisms function indirectly and unconsciously*. Just as the body unconsciously defends itself against disease, so also does the ego unconsciously defend itself against anxiety. For example, **repression** banishes anxiety-arousing wishes and feelings from consciousness. According to Freud, *repression underlies all the other defense mechanisms*. However, because repression is often incomplete, repressed urges may appear as symbols in dreams or as slips of the tongue in casual conversation.

defense mechanisms

in psychoanalytic theory, the ego’s protective methods of reducing anxiety by unconsciously distorting reality.

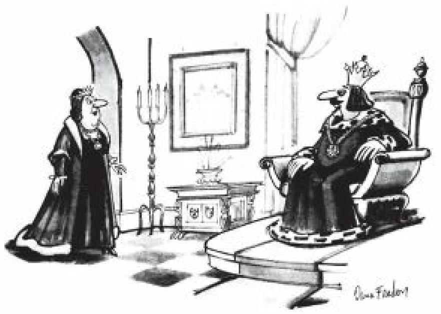
repression

in psychoanalytic theory, the basic defense mechanism that banishes from consciousness anxiety-arousing thoughts, feelings, and memories.

TABLE 55.2 Seven Defense Mechanisms Freud believed that *repression*, the basic mechanism that banishes anxiety-arousing impulses, enables other defense mechanisms, seven of which are listed here as ways a high school student might respond to being cut from the soccer team.

Defense Mechanism	Unconscious Process Employed to Avoid Anxiety-Arousing Thoughts or Feelings	Example of How a 16-Year-Old Defends Against Anxiety After Being Cut from the Soccer Team
Regression	Retreating to an earlier psychosexual stage, where some psychic energy remains fixated	Wants to go to his grandma's house to play cards and eat her chocolate chip cookies
Reaction formation	Switching unacceptable impulses into their opposites	Makes a big show of expressing indifference about being on "the stupid soccer team"
Projection	Disguising one's own threatening impulses by attributing them to others	Talks a lot about how mad his parent is at the coach
Rationalization	Offering self-justifying explanations in place of the real, more threatening unconscious reasons for one's actions	Explains that he wasn't working very hard in the tryouts and could have made the team if he really wanted to
Displacement	Shifting sexual or aggressive impulses toward a more acceptable or less threatening object or person	Yells at his little brother for no real reason
Sublimation	Transferring of unacceptable impulses into socially valued	Decides instead to join the cross-country running team,

	motives	where all are accepted
Denial	Refusing to believe or even perceive painful realities	Insists that there was an error on the team list and he’s going to set things right with the coach



Dana Fradon The New Yorker Collection /The Cartoon Bank

“Good morning, beheaded—uh, I mean beloved.”

Freud believed he could glimpse the unconscious seeping through what we today call “Freudian slips”—as when a financially stressed patient, not wanting any large pills, said, “Please do not give me any bills, because I cannot swallow them.” Freud also viewed jokes as expressions of repressed sexual and aggressive tendencies, and dreams as the “royal road to the unconscious.” The remembered content of dreams (their *manifest content*) he believed to be a censored expression of the dreamer’s unconscious wishes (the dream’s *latent content*). In his dream analyses, Freud searched for patients’ inner conflicts.

> “*I remember your name perfectly but I just can’t think of your face.*”
>
> *Oxford professor W. A. Spooner (1844–1930), famous for his linguistic flip-flops (spoonerisms). Spooner rebuked one student for “fighting a liar in the quadrangle” and another who “hissed my mystery lecture,” adding “You have tasted two worms.”*

AP® EXAM TIP

The differences between these defense mechanisms aren’t always clear. For example, *repression* can be found in most examples. Focus on each example’s key feature. If the key feature is seeing your own impulse in someone else, it’s projection. If the key feature is shifting your aggression from one target to another, it’s displacement.

Left: VStock/Alamy; Right: Richard I’Anson/Getty Images

Regression Faced with a mild stressor, children and young orangutans seek protection and comfort from their caregivers. Freud might have interpreted these behaviors as regression, a retreat to an earlier developmental stage.

✓ Check Your Understanding

Ask Yourself

- Which of Freud’s presumed defense mechanisms have you found yourself employing?

Test Yourself

- According to Freud’s ideas about the three-part personality structure, the _______________ operates on the *reality principle* and tries to balance demands in a way that produces long-term pleasure rather than pain, the _______________ operates on the *pleasure principle* and seeks immediate gratification, and the _______________ represents the voice of our internalized ideals (our *conscience*).
- In the psychoanalytic view, conflicts unresolved during one of the psychosexual stages may lead to _______________ at that stage.
- Freud believed that our defense mechanisms operate _______________ (consciously/unconsciously) and defend us against _______________.

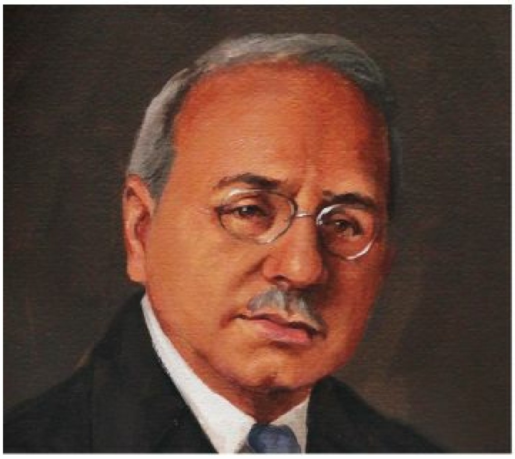
Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

The Neo-Freudian and Later Psychodynamic Theorists

55-4 Which of Freud’s ideas did his followers accept or reject?

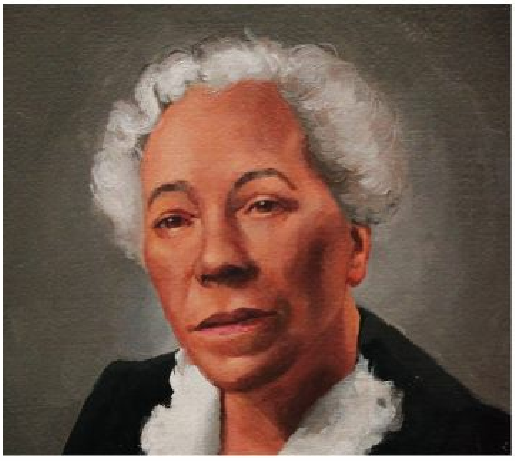
In a historical period when people rarely talked about sex, and certainly not unconscious desires for sex with one’s parent, Freud’s writings sparked intense debate. “In the Middle Ages, they would have burned me,” observed Freud to a friend. “Now they are content with burning my books” (Jones, 1957). Despite the controversy, Freud attracted followers. Several young, ambitious physicians formed an inner circle around their strong-minded leader. These pioneering psychoanalysts, whom we often call *neo-Freudians*, adopted Freud’s interviewing techniques and accepted his basic ideas: the personality structures of id, ego, and superego; the importance of the unconscious; the childhood roots of personality; and the dynamics of anxiety and the defense mechanisms. But they broke off from Freud in two important ways. First, they placed more emphasis on the conscious mind’s role in interpreting experience and in coping with the environment. And second, they doubted that sex and aggression were all-consuming motivations. Instead, they tended to emphasize loftier motives and social interactions.

Alfred Adler and Karen Horney [HORN-eye], for example, agreed with Freud that childhood is important. But they believed that childhood *social*, not sexual, tensions are crucial for personality formation (Ferguson, 2003, 2015). Adler (who gave us the still popular *inferiority complex* idea) had struggled to overcome childhood illnesses and accidents. He believed that much of our behavior is driven by efforts to conquer childhood inferiority feelings that trigger our strivings for superiority and power. Horney said childhood anxiety triggers our desire for love and security. She also opposed Freud’s assumptions that women have weak superegos and suffer “penis envy,” and she attempted to balance his masculine bias.



Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

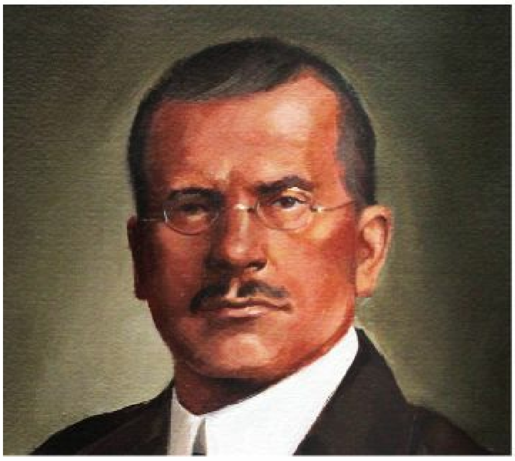
Alfred Adler “The individual feels at home in life and feels his existence to be worthwhile just so far as he is useful to others and is overcoming feelings of inferiority” (*Problems of Neurosis*, 1964).



Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Karen Horney “The view that women are infantile and emotional creatures, and as such, incapable of responsibility and independence is the work of the masculine tendency to lower women’s self-respect” (*Feminine Psychology*, 1932).

Carl Jung [Yoong], Freud’s disciple-turned-dissenter, placed less emphasis on social factors and agreed with Freud that the unconscious exerts a powerful influence. But to Jung, the unconscious contains more than our repressed thoughts and feelings. He believed we also have a **collective unconscious**, a common reservoir of images, or *archetypes*, derived from our species’ universal experiences. Jung said that the collective unconscious explains why, for many people, spiritual concerns are deeply rooted and why people in different cultures share certain myths and images. Most of today's psychologists discount the idea of inherited experiences. But they do believe that our shared evolutionary history shaped some universal dispositions, and that experience can leave *epigenetic* marks affecting gene expression (see Module 14).



Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Carl Jung "From the living fountain of instinct flows everything that is creative; hence the unconscious is the very source of the creative impulse" (*The Structure and Dynamics of the Psyche*, 1960).

collective unconscious

Carl Jung's concept of a shared, inherited reservoir of memory traces from our species' history.

Freud died in 1939. Since then, some of his ideas have been incorporated into the diverse perspectives that make up modern psychodynamic theory. "Most contemporary [psychodynamic] theorists and therapists are not wedded to the idea that sex is the basis of personality," noted Drew Westen (1996). They "do not talk about ids and egos, and do not go around classifying their patients as oral, anal, or phallic characters." What they do assume, with Freud and with much support from today's psychological science, is that much of our mental life is unconscious. With Freud, they also assume that we often struggle with inner conflicts among our wishes, fears, and values, and that childhood shapes our personality and ways of becoming attached to others.

Assessing Unconscious Processes

Flip It Video: Projective Tests

55-5 What are *projective tests*, how are they used, and what are some criticisms of them?

Personality tests reflect the basic ideas of particular personality theories. So, what might be the assessment tool of choice for someone working in the Freudian tradition?

Such a test would need to provide some sort of road into the unconscious—to unearth the residue of early childhood experiences, move beneath surface thoughts, and reveal hidden conflicts and impulses. Objective assessment tools, such as agree-disagree or true-false questionnaires, would be inadequate because they would merely tap the conscious surface.

Projective tests aim to provide this "psychological X-ray" by asking test-takers to describe an ambiguous image or tell a story about it. The clinician may presume that any hopes, desires, and fears that people see in the ambiguous image are projections of their own inner feelings or conflicts.

projective test

a personality test, such as the Rorschach, that provides ambiguous images designed to trigger projection of one's inner dynamics.

Henry Murray (1933) demonstrated a possible basis for such a test at a party hosted by his 11-year-old daughter. Murray engaged the children in a frightening game called "Murder." When shown some photographs after the game, the children perceived the photos as more malicious than they had before the game. These children, it seemed to Murray, had *projected* their inner feelings into the pictures.

A few years later, Murray introduced the **Thematic Apperception Test (TAT)**—a test in which people view ambiguous pictures and then make up stories about them (**Figure 55.2**). Shown a daydreaming boy, those who imagine he is fantasizing about an achievement are presumed to be projecting their own goals. “As a rule,” said Murray, “the subject leaves the test happily unaware that he has presented the psychologist with what amounts to an X-ray of his inner self” (quoted by Talbot, 1999).

Thematic Apperception Test (TAT)

a projective test in which people express their inner feelings and interests through the stories they make up about ambiguous scenes.

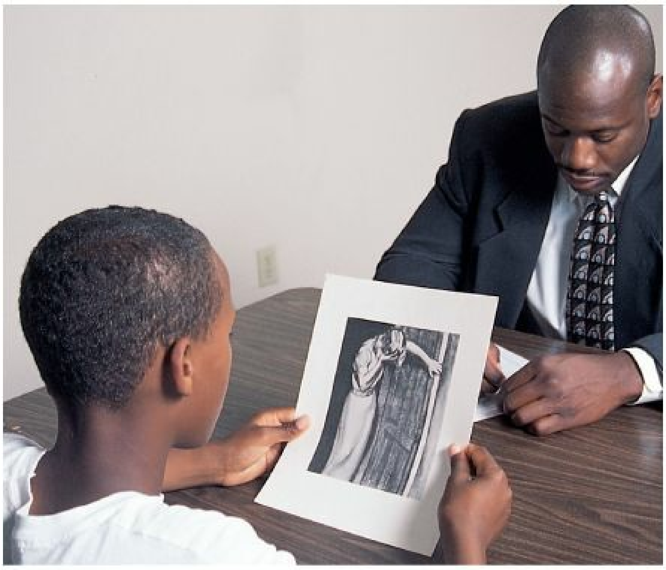


Figure 55.2
Lewis J. Merrim/Science Source

Figure 55.2 **The TAT**

This clinician presumes that the hopes, fears, and interests expressed in this boy’s descriptions of a series of ambiguous pictures in the Thematic Apperception Test (TAT) are projections of his inner feelings.

Numerous studies suggest that Murray was right: The TAT provides a valid and reliable map of people’s implicit motives. For example, such storytelling has been used to assess *achievement* and *affiliation motivation* (Drescher & Schultheiss, 2016; Schultheiss et al., 2014). TAT responses also show consistency over time (Lundy, 1985; Schultheiss & Pang, 2007).

Show people a picture today, and they'll imagine a story similar to one they will tell when, a month later, they see the same picture.

Swiss psychiatrist Hermann Rorschach [ROAR-shock; 1884–1922] created the most widely used projective test. He based his famous **Rorschach inkblot test**, in which people describe what they see in a series of inkblots (**Figure 55.3**), on a childhood game. He and his friends would drip ink on a paper, fold it, and then say what they saw in the resulting blot (Sdorow, 2005). Do you see predatory animals or weapons? Perhaps you have aggressive tendencies. But is this a reasonable assumption? The answer varies.

Rorschach inkblot test

the most widely used projective test; a set of 10 inkblots, designed by Hermann Rorschach; seeks to identify people's inner feelings by analyzing their interpretations of the blots.

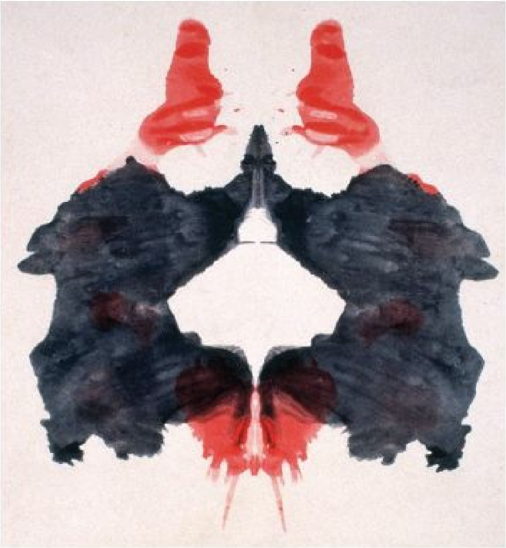

Figure 55.3
Spencer Grant/Science Source

Figure 55.3 The Rorschach test

In this projective test, people tell what they see in a series of symmetrical inkblots. Some who use this test are confident that the interpretation of ambiguous images will reveal unconscious aspects of the test-taker's personality.

Some clinicians cherish the Rorschach test, even offering Rorschach-based assessments of criminals’ violence potential. Others view the test as a source of suggestive leads, an icebreaker, or a revealing interview technique. The Society for Personality Assessment (2005) commends the test’s “responsible use” when “appropriate and justified” (which would *not* include, for example, using the test to infer past childhood sexual abuse).

> “ *We don’t see things as they are; we see things as we are.* ”
>
> *The Talmud*

But the evidence does not persuade its revilers, who insist the Rorschach is no emotional MRI. They argue that only a few of the many Rorschach-derived scores, such as those for cognitive impairment and thought disorder, have demonstrated reliability and validity (Mihura et al., 2013, 2015; Wood et al., 2015). And inkblot assessments have inaccurately diagnosed many healthy adults as pathological (Wood, 2003; Wood et al., 2006). “Even seasoned professionals can be fooled by their intuitions and their faith in tools that lack strong evidence of effectiveness,” warned Scott Lilienfeld, James Wood, and Howard Garb (2001, p. 47). “When a substantial body of research demonstrates that old intuitions are wrong, it is time to adopt new ways of thinking.”

> “ *The Rorschach [inkblot test] has the dubious distinction of being, simultaneously, the most cherished and the most reviled of all psychological assessment tools.* ”
>
> *John Hunsley and J. Michael Bailey (1999)*

Evaluating Freud’s Psychoanalytic Perspective and Modern Views of the Unconscious

55-6 How do contemporary psychologists view Freud’s psychoanalysis, and how has modern research developed our understanding of the unconscious?

Modern Research Contradicts Many of Freud’s Ideas

We critique Freud from a twenty-first-century perspective. Freud did not have access to neurotransmitter or DNA studies, or to all that we have since learned about human development, thinking, and emotion. To criticize his theory by comparing it with today’s thinking is like criticizing Ford’s Model T by comparing it with Tesla’s Model S. How tempting it is to judge the past from the perspective of our present.

> “*Many aspects of Freudian theory are indeed out of date, and they should be: Freud died in 1939, and he has been slow to undertake further revisions.*”
>
> *Psychologist Drew Westen (1998)*

Nevertheless, both Freud’s devotees and his detractors agree that recent research contradicts many of his specific ideas. Today’s developmental psychologists see our *development as lifelong*, not fixed in childhood. They doubt that infants’ neural networks are mature enough to sustain as much emotional trauma as Freud assumed. Some think Freud overestimated parental influence and underestimated peer influence. They also doubt that conscience and gender identity form as the child resolves the Oedipus complex at age 5 or 6. We gain our gender identity earlier, and those who become strongly masculine or feminine do so even without a same-sex parent present. And they note that Freud’s ideas about childhood sexuality arose from stories of childhood sexual abuse told by his female patients—stories that some scholars believe Freud doubted and attributed to his patients’ own childhood sexual wishes and conflicts

(Esterson, 2001; Powell & Boer, 1994). Today, we know that *childhood sexual abuse happens*, and we also understand how Freud's questioning might have created false memories of abuse.

As we saw in Module 24, modern dream research disputes Freud's belief that dreams disguise and fulfill wishes. And slips of the tongue can be explained as competition between similar verbal choices in our memory network. Someone who says "I don't want to do that—it's a lot of brothel" may simply be blending *bother* and *trouble* (Foss & Hakes, 1978). Researchers find little support for Freud's idea that defense mechanisms disguise sexual and aggressive impulses (though our cognitive gymnastics do indeed work to protect our self-esteem). History also has failed to support another of Freud's ideas—that suppressed sexuality causes psychological disorders. From Freud's time to ours, sexual inhibition has diminished; psychological disorders have not.

Psychologists further criticize Freud's theory for its scientific shortcomings. Recall from Module 5 that good scientific theories explain observations and offer testable hypotheses. Freud's theory rests on few objective observations, and parts of it offer few testable hypotheses. For Freud, his own recollections and interpretations of patients' free associations, dreams, and slips—sometimes selected to support his theory—were evidence enough.

What is the most serious problem with Freud's theory? It offers after-the-fact explanations of any characteristic (of one person's smoking, another's fear of horses, another's sexual orientation), yet fails to *predict* such behaviors and traits. If you feel angry at your mother's death, you illustrate Freud's theory because "your unresolved childhood dependency needs are threatened." If you do not feel angry, you again illustrate his theory because “you are repressing your anger.” That “is like betting on a horse after the race has been run” (Hall & Lindzey, 1978, p. 68). A good theory makes testable predictions.

> “*We are arguing like a man who should say, ‘If there were an invisible cat in that chair, the chair would look empty; but the chair does look empty; therefore there is an invisible cat in it’.*”
>
> *C. S. Lewis,* Four Loves, *1958*

So, should psychology post an “Allow Natural Death” order on this old theory? Freud’s supporters object. To criticize Freudian theory for not making testable predictions is, they say, like criticizing baseball for not being an aerobic exercise—something it was never intended to be. Freud never claimed that psychoanalysis was predictive science. He merely claimed that, looking back, psychoanalysts could find meaning in our state of mind (Rieff, 1979).

Freud’s supporters also note that some of his ideas *are* enduring. It was Freud who drew our attention to the unconscious and the irrational, at a time when such ideas were not popular. Today, many researchers study our irrationality (Ariely, 2010; Thaler, 2015). Psychologist Daniel Kahneman won a 2002 Nobel Prize for his studies of our faulty decision making. Freud also drew our attention to the importance of human sexuality, and to the tension between our biological impulses and our social well-being. It was Freud who challenged our self-righteousness, exposed our self-protective defenses, and reminded us of our potential for evil.

> “*Although [Freud] clearly made a number of mistakes in the formulation of his ideas, his understanding of unconscious mental processes was pretty much on target. In fact, it is very consistent with modern neuroscientists’ belief that most mental processes are unconscious.*”
>
> *Nobel Prize-winning neuroscientist Eric Kandel (2012)*

Modern Research Challenges the Idea of Repression

Psychoanalytic theory hinges on the assumption that our mind often *represses* offending wishes, banishing them into the unconscious until they resurface, like long-lost books in a dusty attic. Recover and resolve childhood's conflicted wishes, and emotional healing should follow. Repression became a widely accepted concept, used to explain hypnotic phenomena and psychological disorders. Some psychodynamic followers extended repression to explain apparently lost and recovered memories of childhood traumas (Boag, 2006; Cheit, 1998; Erdelyi, 2006). In one survey, 88 percent of university students believed that painful experiences commonly get pushed out of awareness and into the unconscious (Garry et al., 1994).

Today's researchers agree that we sometimes preserve our self-esteem by neglecting threatening information (Green et al., 2008). Yet many contend that repression, if it ever occurs, is a rare mental response to terrible trauma. Even those who have witnessed a parent's murder or survived Nazi death camps have retained their unrepressed memories of the horror (Helmreich, 1992, 1994; Malmquist, 1986; Pennebaker, 1990). "Dozens of formal studies have yielded not a single convincing case of repression in the entire literature on trauma," concluded personality researcher John Kihlstrom (2006).

> "*During the Holocaust, many children . . . were forced to endure the unendurable. For those who continue to suffer [the] pain is still present, many years later, as real as it was on the day it occurred.*"
>
> *Eric Zillmer, Molly Harrower, Barry Ritzler, and Robert Archer,* The Quest for the Nazi Personality, *1995*

Some researchers do believe that extreme, prolonged stress, such as the stress some severely abused children experience, might disrupt memory by damaging the hippocampus (Schacter, 1996). But the far more common reality is that high stress and associated stress hormones *enhance* memory (Module 32). Indeed, rape, torture, and other traumatic events haunt survivors, who experience unwanted flashbacks. They are seared onto the soul. “You see the babies,” said Holocaust survivor Sally H. (1979). “You see the screaming mothers. You see hanging people. You sit and you see that face there. It’s something you don’t forget.”

The Modern Unconscious Mind

Freud was right about a big idea that underlies today’s psychodynamic thinking: We have limited access to all that goes on in our mind (Erdelyi, 1985, 1988, 2006; Norman, 2010). Our two-track mind has a vast out-of-sight realm. Some researchers even argue that “most of a person’s everyday life is determined by unconscious thought processes” (Bargh & Chartrand, 1999). (Perhaps, for example, you can recall being sad or mad without consciously knowing why.)

AP® EXAM TIP

It’s very important to understand the differences between Freud’s view of the unconscious and modern psychology’s view of the unconscious. Read this section carefully.

Yet many research psychologists now think of the unconscious not as hot passions and repressive censoring but as cooler information processing that occurs without our awareness. To these researchers, the unconscious also involves (as this text explains elsewhere)

- the *schemas* that automatically control our perceptions and interpretations (Module 17).
- the *priming* by stimuli to which we have not consciously attended (Modules 16 and 32).
- the right-hemisphere activity that enables the *split-brain* patient’s left hand to carry out an instruction the patient cannot verbalize (Module 13).
- the *implicit memories* that operate without conscious recall, even among

those with amnesia (Module 33).

- the *emotions* that activate instantly, before conscious analysis (Module 41).
- the *stereotypes* and *implicit prejudice* that automatically and unconsciously influence how we process information about others (Module 77).

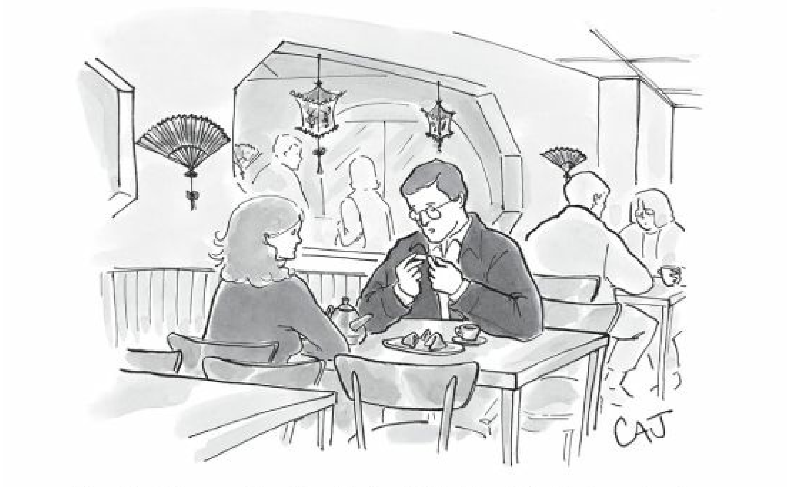
More than we realize, we fly on autopilot. Our lives are guided by off-screen, out-of-sight, unconscious information processing. The unconscious mind is huge. However, our current understanding of unconscious information processing is more like the pre-Freudian view of an underground, unattended stream of thought from which spontaneous behavior and creative ideas surface (Bargh & Morsella, 2008).

Research also supports two of Freud's defense mechanisms. One study demonstrated *reaction formation* (trading unacceptable impulses for their opposite) in men who reported strong antigay attitudes. Compared with those who did not report such attitudes, these antigay men experienced greater arousal when watching videos of homosexual men having sex (Adams et al., 1996). Likewise, some evidence suggests that people who unconsciously identify as homosexual—but who consciously identify as straight—report more negative attitudes toward gays (Weinstein et al., 2012).

Freud's *projection* (attributing our own threatening impulses to others) has also been confirmed. People do tend to see their traits, attitudes, and goals in others (Baumeister et al., 1998b; Maner et al., 2005). Today's researchers call this the *false consensus effect*—the tendency to overestimate the extent to which others share our beliefs and behaviors. People who cheat on their assignments or shoplift petty items "for thrills" tend to think many others do the same. However, defense mechanisms seem motivated less by the sexual and aggressive undercurrents that Freud imagined than by our need to protect our self-image.

Finally, research has supported Freud's idea that we unconsciously defend ourselves against anxiety. Researchers have proposed that one source of anxiety is "the terror resulting from our awareness of vulnerability and death" (Greenberg et al., 1997). Nearly 300 experiments testing **terror-management theory** show that thinking about one's mortality—for example, by writing a short essay on dying and its associated emotions—provokes various terror-management defenses (Burke et al., 2010). For example, death anxiety increases aggression toward rivals and esteem for oneself (Cohen & Solomon, 2011; Koole et al., 2006).

terror-management theory
a theory of death-related anxiety; explores people's emotional and behavioral responses to reminders of their impending death.



Carolita Johnson The New Yorker Collection/The Cartoon Bank

"It says, 'Someday you will die.'"

Faced with a threatening world, people act not only to enhance their self-esteem but also to adhere more strongly to worldviews that answer questions about life's meaning. The prospect of death promotes religious sentiments, and deep religious convictions enable people to be less defensive—less likely to rise in defense of their worldview—when reminded of death (Jonas & Fischer, 2006; Norenzayan & Hansen, 2006). Moreover, when contemplating death, people prioritize their close relationships (Cox & Arndt, 2012; Mikulincer et al., 2003). The actual death of loved ones can provoke protective responses as well. For years, I

[ND] have studied the way people respond to thoughts about death (Hayasaki, 2014; Kashdan et al., 2014). But it took the shock of my own mother's unexpected death to motivate me to start running again and to live a healthier lifestyle. Facing death can inspire us to affirm life.

✓ Check Your Understanding

Ask Yourself

- What understanding and impressions of Freud did you bring to this unit? Are you surprised to find that some of his ideas (especially the big idea of our unconscious mind) had merit?

Test Yourself

- What are three big ideas that have survived from Freud's psychoanalytic theory? What are three ways in which Freud's theory has been criticized?
- Which elements of traditional psychoanalysis have modern-day psychodynamic theorists and therapists retained, and which elements have they mostly left behind?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 55 REVIEW

55-1 What is *personality*, and what theories inform our understanding of personality?

- *Personality* is an individual's characteristic pattern of thinking, feeling, and acting.
- Psychoanalytic (and later psychodynamic) theory and humanistic theory have become part of Western culture. They laid the foundation for later theories, such as trait and social-cognitive theories of personality.

55-2 How did Sigmund Freud's treatment of psychological disorders lead to his view of the unconscious mind, and what was his view of personality?

- *Psychodynamic theories* view personality from the perspective that behavior is a lively (dynamic) interaction between the conscious and unconscious mind. The theories trace their origin to Sigmund Freud's theory of *psychoanalysis.*
- In treating patients whose disorders had no clear physical explanation, Freud concluded that these problems reflected unacceptable thoughts and feelings, hidden away in the *unconscious* mind. To explore this hidden part of a patient's mind, Freud used *free association* and dream analysis.
- Freud believed that personality results from conflict arising from the interaction among the mind's three systems: the *id* (pleasure-seeking impulses), *ego* (reality-oriented executive), and *superego* (internalized set of ideals, or conscience).

55-3 What developmental stages did Freud propose, and how did he think people defended themselves against anxiety?

- Freud believed children pass through five *psychosexual stages* (oral, anal, phallic, latency, and genital).
- According to this view, unresolved conflicts at any stage can leave a person's pleasure-seeking impulses *fixated* (stalled) at that stage.
- For Freud, anxiety was the product of tensions between the demands of the id and superego. The ego copes by using unconscious *defense mechanisms,* such as *repression,* which he viewed as the basic mechanism underlying and enabling all the others.

55-4 Which of Freud's ideas did his followers accept or reject?

- Freud's early followers, the neo-Freudians, accepted many of his ideas. They differed in placing more emphasis on the conscious mind and in stressing social motives more than sexual or aggression motives. Neo-Freudian Carl Jung proposed the *collective unconscious.*
- Contemporary psychodynamic theorists and therapists reject Freud's emphasis on sexual motivation. They stress, with support from modern research findings, the view that much of our mental life is unconscious, and they believe that our childhood experiences influence our adult personality and attachment patterns. Many also believe that our species' shared evolutionary history shaped some universal predispositions.

55-5 What are *projective tests*, how are they used, and what are some criticisms of them?

- *Projective tests* attempt to assess personality by showing people ambiguous stimuli with many possible interpretations; answers reveal unconscious motives.
- The *Thematic Apperception Test (TAT)* and the *Rorschach inkblot test* are two such tests. The TAT provides a valid and reliable roadmap of people's implicit motives, and responses have been shown to be consistent over time. The Rorschach has low reliability and validity, but some clinicians value it as a source of suggestive leads, an icebreaker, or

a revealing interview technique.

55-6 How do contemporary psychologists view Freud's psychoanalysis, and how has modern research developed our understanding of the unconscious?

- Today's psychologists give Freud credit for drawing attention to the vast unconscious, to the struggle to cope with anxiety and sexuality, and to the conflict between biological impulses and social restraints, and for some forms of defense mechanisms.
- But Freud's concept of repression, and his view of the unconscious as a collection of repressed and unacceptable thoughts, wishes, feelings, and memories, have not survived scientific scrutiny. Freud offered after-the-fact explanations, which are hard to test scientifically. And research does not support many of Freud's specific ideas, such as the view that development is fixed in childhood. (We now know it is lifelong.)
- Research confirms that we do not have full access to all that goes on in our mind, though today's science views the unconscious as a separate and parallel track of information processing that occurs outside our awareness. This processing includes schemas that control our perceptions, priming, implicit memories of learned skills, instantly activated emotions, and stereotypes that filter our information processing of others' traits and characteristics.

Multiple-Choice Questions

1. Carly's therapist asks her to simply say what is on her mind rather than responding to specific questions or topics. Her therapist is making use of a technique known as

a. the ego.
b. self-efficacy.
c. sublimation.
d. free association.

   e. identification.

2. The Freudian concept of the ego is best described as
   a. operating on the reality principle.
   b. operating on the pleasure principle.
   c. focusing solely on the morality of an issue.
   d. the repression of disturbing thoughts.
   e. striving for perfection.

3. Ella was an aggressive child in middle school. In high school, she is a successful three-sport athlete because she channels her aggression into sports. Freud would suggest that this is due to the defense mechanism of
   a. repression.
   b. reaction formation.
   c. displacement.
   d. projection.
   e. regression.

4. What did Carl Jung call the shared, inherited reservoir of memory traces from our species' history?
   a. Neurosis
   b. Archetypes
   c. Collective unconscious
   d. Inferiority complex
   e. Terror management

Practice FRQs

1. Nadina is struggling to decide whether to buy a sweater that she really cannot afford. According to Freud, what role would each of the following play in her decision?
   - Id
   - Superego

- Ego

Answer

1 point: In Freud’s view, the id is the impulsive part of our personality. Nadina’s id would cause her to buy the sweater, even though it is too expensive. Page 580

1 point: The superego is Nadina’s conscience and may cause her to feel guilty about buying a sweater that she cannot afford. Page 580

1 point: The ego operates on the reality principle and will help Nadina make the final decision about whether to buy the sweater. The ego will balance the desires of the id with the demands of the superego. Page 580

2. Describe the following two projective tests and state one criticism of these types of test.

- Thematic Apperception Test
- Rorschach inkblot test

(3 points)

Module 56 Humanistic Theories

LEARNING TARGETS

- 56-1 Describe how humanistic psychologists viewed personality, and explain their goal in studying personality.
- 56-2 Explain how humanistic psychologists assessed a person's sense of self.
- 56-3 Describe how humanistic theories have influenced psychology, and discuss the criticisms they have faced.

56-1 How did humanistic psychologists view personality, and what was their goal in studying personality?

By the 1960s, some personality psychologists had become discontented with the sometimes bleak focus on drives and conflicts in psychodynamic theory, and the mechanistic psychology of B. F. Skinner's *behaviorism* (see Modules 27 and 28). Two pioneering theorists—Abraham Maslow (1908–1970) and Carl Rogers (1902–1987)—offered a *third-force perspective* that emphasized human potential. In contrast to Sigmund Freud's emphasis on disorders born out of dark conflicts, these **humanistic theorists** emphasized the ways people strive for self-determination and self-realization. In contrast to behaviorism's scientific objectivity, they studied people through their own self-reported experiences and feelings.

humanistic theories

theories that view personality with a focus on the potential for healthy personal growth.

Abraham Maslow’s Self-Actualizing Person

Maslow proposed that we are motivated by a **hierarchy of needs** (Module 37). If our physiological needs are met, we become concerned with personal safety. If we achieve a sense of security, we then seek to love, to be loved, and to love ourselves. With our love needs satisfied, we seek self-esteem. Having achieved self-esteem, we ultimately seek **self-actualization** (the process of fulfilling our potential) and **self-transcendence** (meaning, purpose, and identity beyond the self).

hierarchy of needs

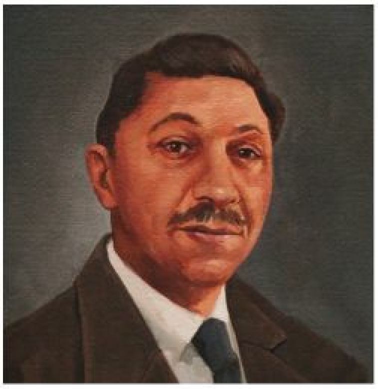
Maslow’s pyramid of human needs, beginning at the base with physiological needs that must first be satisfied before higher-level safety needs and then psychological needs become active.

self-actualization

according to Maslow, one of the ultimate psychological needs that arises after basic physical and psychological needs are met and self-esteem is achieved; the motivation to fulfill one’s potential.

self-transcendence

according to Maslow, the striving for identity, meaning, and purpose beyond the self.



Myers/DeWall, *Myers’ Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Abraham Maslow “Any theory of motivation that is worthy of attention must

> deal with the highest capacities of the healthy and strong person as well as with the defensive maneuvers of crippled spirits” (*Motivation and Personality*, 1970, p. 33).

Maslow (1970) developed his ideas by studying healthy, creative people rather than troubled clinical cases. He based his description of self-actualization on a study of those, such as Abraham Lincoln, who seemed notable for their meaningful and productive lives. Maslow reported that such people shared certain characteristics: They were self-aware and self-accepting, open and spontaneous, loving and caring, and not paralyzed by others’ opinions. Secure in their sense of who they were, their interests were problem-centered rather than self-centered. They focused their energies on a particular task, one they often regarded as their mission in life. Most enjoyed a few deep relationships rather than many superficial ones. Many had been moved by spiritual or personal *peak experiences*. These, said Maslow, are mature adult qualities found in those who have learned enough about life to be compassionate, to have outgrown their mixed feelings toward their parents, to have found their calling, to have “acquired enough courage to be unpopular, to be unashamed about being openly virtuous.”

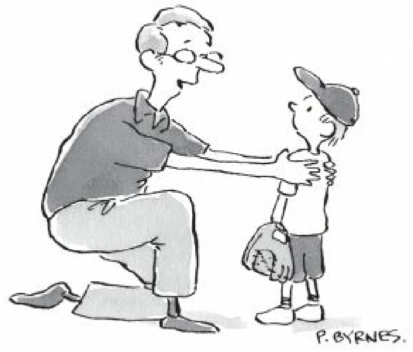
Carl Rogers’ Person-Centered Perspective

Fellow humanistic psychologist Carl Rogers agreed with much of Maslow’s thinking. Rogers’ *person-centered perspective* held that people are basically good and are endowed with self-actualizing tendencies. Unless thwarted by an environment that inhibits growth, each of us is like an acorn, primed for growth and fulfillment. Rogers (1980) believed that a growth-promoting social climate provides:

- *Acceptance:* When people are *accepting,* they offer **unconditional positive regard**, an attitude of grace that values us even knowing our failings. It is a profound relief to drop our pretenses, confess our worst feelings, and discover that we are still accepted. In a good marriage, a close family, or an intimate friendship, we are free to be spontaneous without fearing the loss of others’ esteem.
- *Genuineness:* When people are *genuine,* they are open with their own feelings, drop their facades, and are transparent and self-disclosing.
- *Empathy:* When people are *empathic,* they share and mirror other’s feelings and reflect their meanings. “Rarely do we listen with real understanding, true empathy,” said Rogers. “Yet listening, of this very special kind, is one of the most potent forces for change that I know.” (When others talk do you generally listen closely, or just await your turn to talk?)

unconditional positive regard

a caring, accepting, nonjudgmental attitude, which Carl Rogers believed would help people develop self-awareness and self-acceptance.

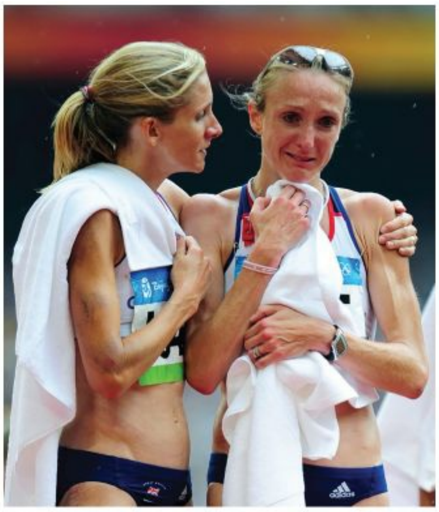


Pat Byrnes The New Yorker Collection
/The Cartoon Bank

"Just remember, son, it doesn't matter whether you win or lose—unless you want Daddy's love."

A father *not* offering unconditional positive regard:

So, some things get better with *age*: *a*cceptance, *g*enuineness, and *e*mpathy. These are, Rogers believed, the water, sun, and nutrients that enable people to grow like vigorous oak trees. For "as persons are accepted and prized, they tend to develop a more caring attitude toward themselves" (Rogers, 1980, p. 116). As persons are empathically heard, "it becomes possible for them to listen more accurately to the flow of inner experiencings."



DYLAN MARTINEZ/REUTERS/Newscom

The picture of empathy Being open and sharing confidences is easier when the listener shows real understanding. Within such relationships we can relax and fully express our true selves. Consider a conversation when you knew someone was waiting for their turn to speak instead of listening to you. Now consider the last time someone heard you with empathy. How did those two experiences differ?

Writer Calvin Trillin (2006) recalled an example of parental acceptance and genuineness at a camp for children with severe disorders, where his wife, Alice, worked. L., a “magical child,” had genetic diseases that meant she had to be tube-fed and could walk only with difficulty. Alice recalled,

> One day, when we were playing duck-duck-goose, I was sitting behind her and she asked me to hold her mail for her while she took her turn to be chased around the circle. It took her a while to make the circuit, and I had time to see that on top of the pile [of mail] was a note from her mom. Then I did something truly awful. . . . I simply had to know what this child’s parents could have done to make her so spectacular, to make her the most optimistic, most enthusiastic, most hopeful human being I had ever encountered. I snuck a quick look at the note, and my eyes fell on this sentence: “If God had given us all of the children in the world to choose from, L., we would only have chosen you.” Before L. got back to her place in the circle, I showed the note to Bud, who was sitting next to me. “Quick. Read this,” I whispered. “It’s the secret of life.”

Maslow and Rogers would have smiled knowingly. For them, a central feature of personality is one’s **self-concept**—all the thoughts and feelings we have in response to the question, “Who am I?” If our self-concept is positive, we tend to act and perceive the world positively. If it is negative—if in our own eyes we fall far short of our *ideal self*—said Rogers, we feel dissatisfied and unhappy. A worthwhile goal for therapists, parents, teachers, and friends is therefore, he said, to help others know, accept, and be true to themselves.

self-concept

all our thoughts and feelings about ourselves, in answer to the question, “Who am I?”

Assessing the Self

56-2 How did humanistic psychologists assess a person’s sense of self?

Humanistic psychologists sometimes assessed personality by asking people to fill out questionnaires that would evaluate their self-concept. One questionnaire, inspired by Carl Rogers, asked people to describe themselves both as they would *ideally* like to be and as they *actually* are. When the ideal and the actual self are nearly alike, said Rogers, the self-concept is positive. Assessing his clients’ personal growth during therapy, he looked for successively closer ratings of actual and ideal selves.

Some humanistic psychologists believed that any standardized assessment of personality, even a questionnaire, is depersonalizing. Rather than forcing the person to respond to narrow categories, these humanistic psychologists presumed that interviews and intimate conversation would provide a better understanding of each person’s unique experiences. Some researchers believe our identity may be revealed using the *life story approach*—collecting a rich narrative detailing each person’s unique life history (Adler et al., 2016; McAdams & Guo, 2015). A lifetime of stories can show more of a person’s complete identity than can the responses to a few questions.

Evaluating Humanistic Theories

56-3 How have humanistic theories influenced psychology? What criticisms have they faced?

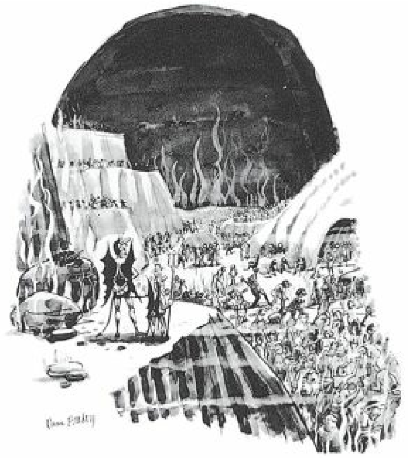
One thing said of Freud can also be said of the humanistic psychologists: Their impact has been pervasive. Maslow's and Rogers' ideas have influenced counseling, education, child raising, and management. And they laid the groundwork for today's scientific *positive psychology* subfield (Module 44).

These theorists have also influenced—sometimes in unintended ways—much of today's popular psychology. Is a positive self-concept the key to happiness and success? Do acceptance and empathy nurture positive feelings about ourselves? Are people basically good and capable of self-improvement? Many people answer *Yes, Yes,* and *Yes.* In 2006, U.S. high school students reported notably higher self-esteem and greater expectations of future career success than did students living in 1975 (Twenge & Campbell, 2008). Given a choice, today's North American college students mostly say they'd rather get a self-esteem boost, such as a compliment or good grade on a paper, than enjoy a favorite food (Bushman et al., 2011). Humanistic psychology's message has been heard.

But the prominence of the humanistic perspective set off a backlash of criticism. First, said the critics, its concepts are vague and subjective. Consider Maslow's description of self-actualizing people as open, spontaneous, loving, self-accepting, and productive. Is this a scientific description? Or is it merely a description of the theorist's own values and ideals? Maslow, noted M. Brewster Smith (1978), offered impressions of his own personal heroes. Imagine another theorist who began with a different set of heroes—perhaps Napoleon, John D. Rockefeller, Sr., and U.S. President Donald Trump. This theorist would likely describe self-actualizing people as "undeterred by others' opinions," "motivated to achieve," and "comfortable with power."

Critics also objected to the idea that, as Rogers (1985) put it, "The only question which matters is, ‘Am I living in a way which is deeply satisfying to me, and which truly expresses me?’” This emphasis on *individualism*—trusting and acting on one’s feelings, being true to oneself, fulfilling oneself—could lead to self-indulgence, selfishness, and an erosion of moral restraint (Campbell & Specht, 1985; Wallach & Wallach, 1983). Imagine working on a group project with people who refuse to complete any task that is not deeply satisfying or does not truly express their identity.

Humanistic psychologists have replied that a secure, nondefensive self-acceptance is actually the first step toward loving others. Indeed, people who feel intrinsically liked and accepted—for who they are, not just for their achievements—exhibit less defensive attitudes (Schimel et al., 2001). Those feeling liked and accepted by a romantic partner report being happier in their relationships and acting more kindly toward their partner (Gordon & Chen, 2010).



Dana Fradon The New Yorker Collection
/The Cartoon Bank

“We do pretty well when you stop to think that people are basically good.”

A final accusation leveled against humanistic psychology is that it is *naive*—that it fails to appreciate the reality of our human capacity for evil (May, 1982). Faced with climate change, overpopulation, terrorism, and the spread of nuclear weapons, we may become apathetic from either of two rationalizations. One is a starry-eyed optimism that denies the threat (“People are basically good; everything will work out”). The other is a dark despair (“It’s hopeless; why try?”). Action requires enough realism to fuel concern and enough optimism to provide hope. (Pessimism often fulfills its own predictions by restraining our efforts at change.) Humanistic psychology, say the critics, encourages the needed hope but not the equally necessary realism.

✓ Check Your Understanding

Ask Yourself

- Have you had someone in your life who accepted you unconditionally? How did this person help you to know yourself better and to develop a better image of yourself?

Test Yourself

- How did humanistic psychology provide a fresh perspective?
- What does it mean to be empathic? How about self-actualized? Which humanistic psychologists used these terms?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 56 REVIEW

56-1 How did humanistic psychologists view personality, and what was their goal in studying personality?

- The *humanistic* psychologists' view of personality focused on the potential for healthy personal growth and people's striving for self-determination and self-realization.
- Abraham Maslow proposed that human motivations form a *hierarchy of needs;* if basic needs are fulfilled, people will strive toward *self-actualization* and *self-transcendence.*
- Carl Rogers' person-centered perspective suggested that the ingredients of a growth-promoting environment are acceptance (including *unconditional positive regard*), genuineness, and empathy.
- *Self-concept* was a central feature of personality for both Maslow and Rogers.

56-2 How did humanistic psychologists assess a person's sense of self?

- Some rejected any standardized assessments and relied on interviews and conversations.
- Rogers sometimes used questionnaires in which people described their ideal and actual selves, which he later used to judge progress during therapy.

56-3 How have humanistic theories influenced psychology? What criticisms have they faced?

- Humanistic psychology helped renew interest in the concept of self, and also laid the groundwork for today's scientific subfield of positive psychology.

- Critics have said that humanistic psychology’s concepts were vague and subjective, its values self-centered, and its assumptions naively optimistic.

Multiple-Choice Questions

1. Maslow and Rogers would explain that adolescents who are struggling to form their identity are seeking to discover their

a. self-transcendence.
b. self-actualization.
c. self-esteem.
d. self-worth.
e. self-concept.

2. What do we call the process of fulfilling our potential?

a. Free association
b. Self-efficacy
c. Unconditional positive regard
d. Self-concept
e. Self-actualization

3. Humanistic psychologists may assess personality by

a. asking a person to compare their ideal self to their actual self.
b. asking people to fill out lengthy questionnaires about their beliefs.
c. getting people to describe what they see in ambiguous inkblots.
d. having a person describe their dreams.
e. putting people in a stressful situation to see how they behave under pressure.

4. Which of the following is an example of unconditional positive regard?

a. Mr. and Mrs. Prohaska, who have been married for 37 years, credit the success of their marriage to the fact that each has been able to accept the faults of the other without criticism.
b. Seven-year-old Michaela is only given her allowance when she does her chores.

c. Ms. Lopez, a second grade teacher, only gives smiley-face stickers to students who sit quietly at their desks during math.
d. John got a promotion and a raise at work after filling in for a sick manager one day and doing a better job than the manager.
e. Chen’s parents usually praise him when he does well and ignore him when he engages in minor misbehavior.

Practice FRQs

1. As a new student, Canya is hoping to fit in. If the students at her new school were embracing the ideas of Carl Rogers, how would each of these principles affect how they treat Canya?

- Acceptance
- Genuineness
- Empathy

Answer

1 point: When employing Rogers’ *acceptance*, people show unconditional positive regard—others are accepted despite their faults and failures. Canya will probably make mistakes at her new school, but the established students would understand that it is because she is new and not judge her because of them. Page 592

1 point: When following Rogers’ *genuineness*, people are open with their feelings. The students at the school would be themselves around Canya and provide her with advice about how to fit in. Page 592

1 point: When employing Rogers’ *empathy*, people share and mirror the feelings of others. In this case, students might remember a time that they were in a new place and understand how Canya is feeling. Page 592

2. Describe three criticisms that have been made of humanistic psychology.

(3 points)

Module **57 Trait Theories**

LEARNING TARGETS

- 57-1 Explain how psychologists use traits to describe personality.
- 57-2 Discuss some common misunderstandings about introversion.
- 57-3 Describe *personality inventories*, and discuss their strengths and weaknesses as trait-assessment tools.
- 57-4 Identify the traits that seem to provide the most useful information about personality variation.
- 57-5 Discuss whether research supports the consistency of personality traits over time and across situations.

57-1 How do psychologists use traits to describe personality?

Rather than focusing on unconscious forces and thwarted growth opportunities, some researchers attempt to define personality in terms of stable and enduring behavior patterns, such as Lady Gaga's openness to new experiences and her self-discipline. This perspective can be traced in part to a remarkable meeting in 1919, when Gordon Allport, a curious 22-year-old psychology student, interviewed Sigmund Freud in Vienna. Allport soon discovered just how preoccupied the founder of psychoanalysis was with finding hidden motives, even in Allport's own behavior during the interview. That experience ultimately led Allport to do what Freud did not do: to describe personality in terms of fundamental **traits**, or people's characteristic behaviors and conscious motives (such as the curiosity that actually motivated Allport to see Freud). Meeting Freud, said Allport, “taught me that [psychoanalysis], for all its merits, may plunge too deep, and that psychologists would do well to give full recognition to manifest motives before probing the unconscious.” Allport came to define personality in terms of identifiable behavior patterns. He was concerned less with *explaining* individual traits than with *describing* them.

trait
a characteristic pattern of behavior or a disposition to feel and act in certain ways, as assessed by self-report inventories and peer reports.

Like Allport, Isabel Briggs Myers (1987) and her mother, Katharine Briggs, wanted to describe important personality differences. They attempted to sort people according to Carl Jung’s *personality types,* based on their responses to 126 questions. The *Myers-Briggs Type Indicator (MBTI),* available in 20+ languages, has been taken by millions of people, mostly for counseling, leadership training, and work-team development (CPP, 2017). It offers choices, such as “Do you usually value sentiment more than logic, or value logic more than sentiment?” Then it counts the test-taker’s preferences, labels them as indicating, say, a “feeling type” or “thinking type,” and feeds them back to the person in complimentary terms. Feeling types, for example, are told they are “sympathetic, appreciative, and tactful”; thinking types are told they are “good at analyzing.” (Every type has its strengths, so everyone is affirmed.)

Most people agree with their announced MBTI type profile, which mirrors their declared preferences. They may also accept their label as a basis for being matched with work partners and tasks that supposedly suit their temperaments. But research suggests that people should not blindly accept the validity of their test results. A National Research Council report noted that despite the test’s popularity in business and career counseling, its use has outrun research on its validity as a job performance predictor:

“The popularity of this instrument in the absence of proven scientific worth is troublesome” (Druckman & Bjork, 1991, p. 101; see also Pittenger, 1993). Although research on the MBTI has been accumulating since those cautionary words were expressed, the test remains mostly a counseling and coaching tool, not a research instrument.

James Devaney/Getty Images

Stephen Colbert: The extravert Trait labels such as *extraversion* can describe our temperament and typical behaviors.

Exploring Traits

Classifying people as one or another distinct personality type fails to capture their full individuality. We are each a unique complex of multiple traits. So how else could we describe our personalities? We might describe an apple by placing it along several trait dimensions—relatively large or small, red or green, sweet or tart. By placing people on several trait dimensions simultaneously, psychologists can describe countless individual personality variations. (Remember from Module 18 that variations on just three color dimensions—*hue*, *saturation*, and *brightness*—create many thousands of colors.)

What trait dimensions describe personality? If you were looking at profiles on an Internet dating site, what personality traits would give you the best sense for each person? Allport and his associate H. S. Odbert (1936) counted all the words in an unabridged dictionary with which one could describe people. There were almost 18,000! How, then, could psychologists condense the list to a manageable number of basic traits?

AP® EXAM TIP

You are not likely to be asked questions about the specific traits in Figure 57.1. Focus instead on the two main dimensions (extraversion–introversion and stability–instability), and use the traits to get a sense of what the main dimensions mean.

Factor Analysis

▶ **Flip It Video: Factor Analysis**

One technique is *factor analysis*, a statistical procedure that identifies clusters (factors) of test items that tap basic components of a trait (McCabe & Fleeson, 2016). Imagine that people who describe themselves as outgoing also tend to say that they like excitement and practical jokes and dislike quiet reading. Such a statistically correlated cluster of behaviors reflects a basic factor, or trait—in this case, *extraversion.*

British psychologists Hans Eysenck and Sybil Eysenck [EYE-zink] believed that we can reduce many of our normal individual variations to two dimensions: *extraversion–introversion* and *emotional stability–instability* (**Figure 57.1**). People in 35 countries around the world, from China to Uganda to Russia, have taken the *Eysenck Personality Questionnaire.* When their answers were analyzed, the extraversion and emotionality factors inevitably emerged as basic personality dimensions (Eysenck, 1990, 1992). The Eysencks believed, and research confirms, that these factors are genetically influenced.

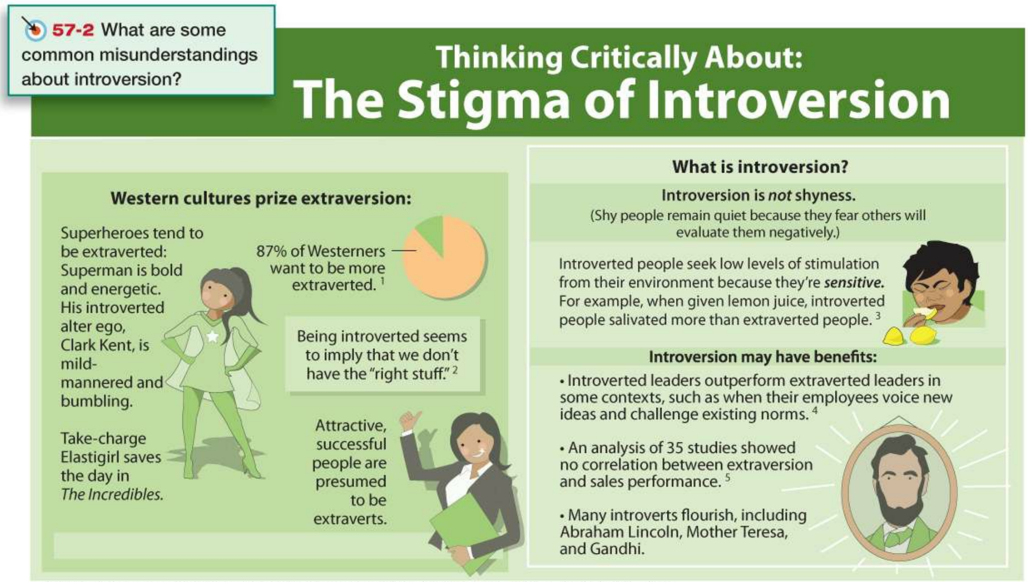
Figure 57.1 Two personality dimensions

Mapmakers can tell us a lot by using two axes (north–south and east–west). Two primary personality factors (extraversion–introversion and stability–instability) are similarly useful as axes for describing personality variation. Varying combinations define other, more specific traits (Eysenck & Eysenck, 1963). Those who are naturally introverted, such as primatologist Jane Goodall, may be particularly gifted in field studies. Successful entertainers, including Katy Perry, are often natural extraverts.

Biology and Personality

Brain-activity scans of extraverts add to the growing list of traits and mental states now being explored with brain-imaging procedures. Such studies indicate that extraverts seek stimulation because their normal brain arousal is relatively low. For example, PET scans have shown that a frontal lobe area involved in behavior inhibition is less active in extraverts than in introverts (Johnson et al., 1999). Dopamine and dopamine-related neural activity tend to be higher in extraverts (Kim et al., 2008; Wacker et al., 2006).

Our biology influences our personality in other ways as well. Recall from the twin and adoption studies in Module 14 that our genes have much to say about the behavioral style that shape our personality. Jerome Kagan, for example, has attributed differences in children's shyness and inhibition to their autonomic nervous system reactivity (see Thinking Critically About: The Stigma of Introversion). Those with a reactive autonomic nervous system respond to stress with greater anxiety and inhibition. The fearless, curious child may become the rock-climbing or fast-driving adult.



57-2 What are some common misunderstandings about introversion?

Thinking Critically About:

The Stigma of Introversion

Western cultures prize extraversion:

Superheroes tend to be extraverted: Superman is bold and energetic. His introverted alter ego, Clark Kent, is mild-mannered and bumbling.

Take-charge Elastigirl saves the day in *The Incredibles.*

87% of Westerners want to be more extraverted.[1]

Being introverted seems to imply that we don't have the "right stuff."[2]

Attractive, successful people are presumed to be extraverts.

What is introversion?

Introversion is *not* shyness.

(Shy people remain quiet because they fear others will evaluate them negatively.)

Introverted people seek low levels of stimulation from their environment because they're ***sensitive.*** For example, when given lemon juice, introverted people salivated more than extraverted people.[3]

Introversion may have benefits:

- Introverted leaders outperform extraverted leaders in some contexts, such as when their employees voice new ideas and challenge existing norms.[4]
- An analysis of 35 studies showed no correlation between extraversion and sales performance.[5]
- Many introverts flourish, including Abraham Lincoln, Mother Teresa, and Gandhi.

1. Hudson & Roberts, 2014. 2. Cain, 2012. 3. Corcoran, 1964. 4. Grant et al., 2011. 5. Barrick et al., 2001.

Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Personality differences among dogs (in energy, affection, reactivity, and curious intelligence) are as evident, and as consistently judged, as personality differences among humans (Gosling et al., 2003; Jones & Gosling, 2005). Monkeys, bonobos, chimpanzees, orangutans, and even birds and fish also have distinct and stable personalities (Latzman et al., 2015; Pennisi, 2016; Weiss et al., 2006, 2015). Among the Great Tit (a European relative of the American chickadee), bold birds more quickly inspect new objects and explore trees (Groothuis & Carere, 2005; Verbeek et al., 1994). Through selective breeding, researchers can produce bold or shy birds. Both have their place in natural history: In lean years, bold birds are more likely to find food; in abundant years, shy birds feed with less risk.

Chris Cardone

Pups have personality

Assessing Traits

57-3 What are *personality inventories*, and what are their strengths and weaknesses as trait-assessment tools?

If stable and enduring traits guide our actions, can we devise valid and reliable tests of them? Several trait assessment techniques exist—some more valid than others. Some provide quick assessments of a single trait, such as extraversion, anxiety, or self-esteem. **Personality inventories**—longer questionnaires covering a wide range of feelings and behaviors—assess several traits at once.

personality inventory

a questionnaire (often with *true-false* or *agree-disagree* items) on which people respond to items designed to gauge a wide range of feelings and behaviors; used to assess selected personality traits.

The classic personality inventory is the **Minnesota Multiphasic Personality Inventory (MMPI)**. Although the MMPI was originally developed to identify emotional disorders, it also assesses people's personality traits. One of its creators, Starke Hathaway (1960), compared his effort with that of Alfred Binet (who, as you will see in Module 61, developed the first intelligence test by selecting items that identified children who would probably have trouble progressing normally in French schools). Like Binet's items, the MMPI items were **empirically derived**: From a large pool of items, Hathaway and his colleagues selected those on which particular diagnostic groups differed. "Nothing in the newspaper interests me except the comics" may seem superficial, but it just so happened that depressed people were more likely to answer *True*. (Nevertheless, people have had fun spoofing the MMPI with their own mock items: "Weeping brings tears to my eyes," "Frantic screams make me nervous," and "I stay in the bathtub until I look like a raisin" [Frankel et al., 1983].) The researchers grouped the questions into 10 clinical scales, including scales that assess depressive tendencies, masculinity–femininity, and introversion–extraversion. Today's MMPI-2 has additional scales that assess work attitudes, family problems, and anger.

Minnesota Multiphasic Personality Inventory (MMPI)

the most widely researched and clinically used of all personality tests. Originally developed to identify emotional disorders (still considered its most appropriate use), this test is now used for many other screening purposes.

empirically derived test

a test (such as the MMPI) created by selecting from a pool of items those that discriminate between groups.

Whereas most projective tests (such as the Rorschach) are scored subjectively, personality inventories are scored objectively. Objectivity does not, however, guarantee validity. For example, individuals taking the MMPI for employment purposes can give socially desirable answers to create a good impression. But in so doing they may also score high on a *lie scale* that assesses faking (as when people respond *False* to a universally true statement such as "I get angry sometimes"). The objectivity of the MMPI has contributed to its popularity and its translation into more than 100 languages.

FYI

Psychologists working from the trait perspective have devised scientifically sound *personality inventories* that assess our traits. But beware of the hundreds of online self-assessments that are neither reliable nor valid.

The Big Five Factors

57-4 Which traits seem to provide the most useful information about personality variation?

AP® EXAM TIP

Table 57.1 is an excellent summary of the Big Five personality factors and what they mean. Be able to apply the traits to describe behavior. For example, you should be able to explain how high levels of agreeableness might help someone with a particular task.

Today's trait researchers believe that simple trait factors, such as the Eysencks' introversion–extraversion and stability–instability dimensions, are important, but they do not tell the whole story. A slightly expanded set of factors developed by Robert McCrae and Paul Costa—dubbed the *Big Five*—does a better job (Costa & McCrae, 2011). If a test specifies where you are on the five dimensions (conscientiousness, agreeableness, neuroticism, openness, and extraversion; see **Table 57.1**), it has said much of what there is to say about your personality.

TABLE 57.1 The "Big Five" Personality Factors Researchers use self-r inventories and peer reports to assess and score the Big Five personali

(*Memory tip:* Picturing a **CANOE** will help you recall these.)	
Disorganized, careless, impulsive	Ruthless, suspicious, uncooperative	
Calm, secure, self-satisfied	Neuroticism (emotional stability vs. instability)
Practical, prefers routine, conforming	
Retiring, sober, reserved	Extraversion

Source: Information from McCrae & Costa (1986, 2008).

Around the world—across 56 nations and 29 languages in one study (Schmitt et al., 2007)—people describe others in terms roughly consistent with this list. The Big Five—today's "common currency for personality psychology" (Funder, 2001)—has been the most active personality research topic since the early 1990s and is currently our best approximation of the basic trait dimensions.

Big Five research has explored various questions:

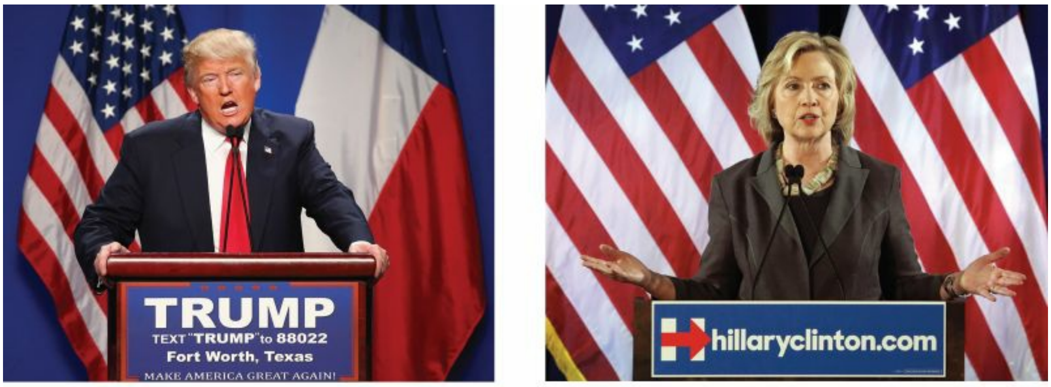
- ***How stable are these traits?*** One research team analyzed 1.25 million participants ages 10 to 65. They learned that personality continues to develop and change through late childhood and adolescence. Up to age 40, we show signs of a *maturity principle:* We become more conscientious and agreeable and less neurotic (emotionally unstable) (Bleidorn, 2015; Milojev & Sibley, 2016). Great apes show similar personality maturation (Weiss & King, 2015). After age 40, our traits further stabilize.
- ***How heritable are these traits?*** Heritability (the extent to which individual differences are attributable to genes) generally runs about 40 percent for each dimension (Vukasovi´c & Bratko, 2015). Many genes, each having small effects, combine to influence our traits (McCrae et al., 2010; van den Berg et al., 2016).
- ***Do these traits reflect differing brain structure?*** The size and thickness

of brain tissue correlates with several Big Five traits (DeYoung et al., 2010; Grodin & White, 2015; Riccelli et al., 2017). For example, those who score high on conscientiousness tend to have a larger frontal lobe area that aids in planning and controlling behavior. Brain connections also influence the Big Five traits (Adelstein et al., 2011). People high in neuroticism (emotional instability) have brains that are wired to experience stress intensely (Shackman et al., 2016; Xu et al., 2012).

- ***Do these traits reflect birth order?*** After controlling for other variables such as family size, are first-born children, for example, more conscientious and agreeable? Contrary to popular opinion, several massive studies failed to find any association between birth order and personality (Damian & Roberts, 2015; Harris, 2009; Rohrer et al., 2015).
- ***How well do these traits apply to various cultures?*** The Big Five dimensions describe personality in various cultures reasonably well (Fetvadjiev et al., 2017; Schmitt et al., 2007; Vazsonyi et al., 2015). After studying people from 50 cultures, Robert McCrae and 79 co-researchers concluded that “features of personality traits are common to all human groups” (2005).
- ***Do the Big Five traits predict our actual behaviors?*** *Yes.* If people report being outgoing, conscientious, and agreeable, “they probably are telling the truth,” reports McCrae (2011). Conscientiousness and agreeableness predict workplace success, and agreeableness predicts helpfulness (Habashi et al., 2016; Sackett & Walmsley, 2014). Traits also characterize certain career paths. For example, U.S. politicians often have “big” personalities, outscoring the general public on extraversion, agreeableness, conscientiousness, and emotional stability (low neuroticism) (Hanania, 2017). Our traits also appear in our language patterns. In text messaging, extraversion predicts use of personal pronouns. Neuroticism predicts negative-emotion words (Holtgraves, 2011).

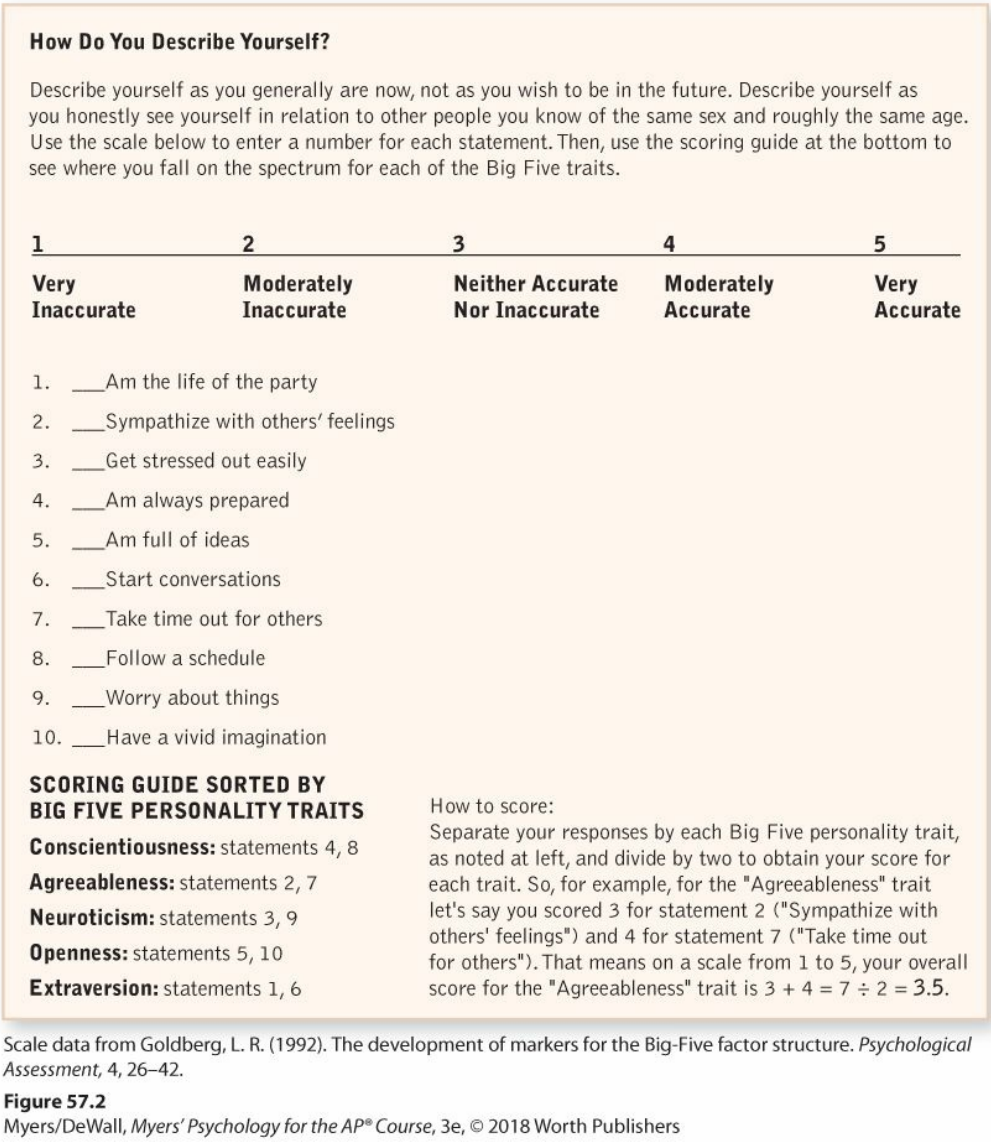
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

How do you vote? Let me count the likes. Researchers can use your Facebook likes to predict your Big Five traits, your opinions, and your political attitudes (Youyou et al., 2015). Companies gather these "big data" for advertisers (who then personalize the ads you see). They do the same for political candidates, who can target you with persuasive messages. In the 2016 U.S. presidential campaign, "both sides were certainly using big data . . . to win over voters," says researcher Michal Kosinski (Zakaria, 2017).



Left: Tom Pennington/Getty Images; Right: KENA BETANCUR/Getty Images

By exploring such questions, Big Five research has sustained trait psychology and renewed appreciation for the importance of personality. (To describe your personality, try the brief self-assessment in **Figure 57.2**.) Traits matter. In the next section, we will see that situations matter, too.



How Do You Describe Yourself?

Describe yourself as you generally are now, not as you wish to be in the future. Describe yourself as you honestly see yourself in relation to other people you know of the same sex and roughly the same age. Use the scale below to enter a number for each statement. Then, use the scoring guide at the bottom to see where you fall on the spectrum for each of the Big Five traits.

1	2	3	4	5
Very Inaccurate	**Moderately Inaccurate**	**Neither Accurate Nor Inaccurate**	**Moderately Accurate**	**Very Accurate**

1. ___Am the life of the party
2. ___Sympathize with others' feelings
3. ___Get stressed out easily
4. ___Am always prepared
5. ___Am full of ideas
6. ___Start conversations
7. ___Take time out for others
8. ___Follow a schedule
9. ___Worry about things
10. ___Have a vivid imagination

SCORING GUIDE SORTED BY BIG FIVE PERSONALITY TRAITS

Conscientiousness: statements 4, 8

Agreeableness: statements 2, 7

Neuroticism: statements 3, 9

Openness: statements 5, 10

Extraversion: statements 1, 6

How to score:
Separate your responses by each Big Five personality trait, as noted at left, and divide by two to obtain your score for each trait. So, for example, for the "Agreeableness" trait let's say you scored 3 for statement 2 ("Sympathize with others' feelings") and 4 for statement 7 ("Take time out for others"). That means on a scale from 1 to 5, your overall score for the "Agreeableness" trait is 3 + 4 = 7 ÷ 2 = 3.5.

Scale data from Goldberg, L. R. (1992). The development of markers for the Big-Five factor structure. *Psychological Assessment*, 4, 26–42.

Figure 57.2 The Big Five self-assessment

Check Your Understanding

Ask Yourself

- Before trying the self-assessment in Figure 57.2, where would you have placed yourself on the Big Five personality dimensions? Where might your family and friends place you? Did the actual results surprise you, and do you think these results would surprise them?

Test Yourself

- Which two primary dimensions did Hans Eysenck and Sybil Eysenck propose for describing personality variation?

- What are the Big Five personality factors, and why are they scientifically useful?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Evaluating Trait Theories

57-5 Does research support the consistency of personality traits over time and across situations?

Are our personality traits stable and enduring? Or does our behavior depend on where and with whom we find ourselves? In some ways, our personality seems stable. Cheerful, friendly children tend to become cheerful, friendly adults. At a college reunion, I [DM] was amazed to find that my jovial former classmates were still jovial, the shy ones still shy, the happy-seeming people still smiling and laughing *50 years later*. But it's also true that a fun-loving jokester can suddenly turn serious and respectful at a job interview. New situations and major life events can shift the personality traits we express. Becoming unemployed, for example, may make us less agreeable and open-minded (Boyce et al., 2015).

The Person-Situation Controversy

Our behavior is influenced by the interaction of our inner disposition with our environment. Still, the question lingers: Which is more important? When we explore this *person-situation controversy*, we look for genuine personality traits that persist over time *and* across situations. Are some people dependably conscientious and others unreliable, some cheerful and others dour, some friendly and outgoing and others shy? If we are to consider friendliness a trait, friendly people must act friendly at different times and places. Do they?

FYI

Roughly speaking, the temporary, external influences on behavior are the focus of *social psychology*, and the enduring, inner influences are the focus of *personality psychology*. In actuality, behavior always depends on the interaction of persons with situations.

In earlier units, we considered research that has followed lives through time. We noted that some scholars (especially those who study infants) are impressed with personality change; others are struck by personality stability during adulthood. As **Figure 57.3** illustrates, data from 152 long-term *(longitudinal)* studies reveal that personality trait scores are positively correlated with scores obtained seven years later, and that as people grow older their personality stabilizes. Interests may change—the avid tropical-fish collector may become an avid gardener. Careers may change—the determined salesperson may become a determined social worker. Relationships may change—the hostile spouse may start over and antagonize a new partner. But most people recognize just who they are, as Robert McCrae and Paul Costa noted (1994), “and it is well that they do. A person’s recognition of the inevitability of his or her one and only personality is . . . the culminating wisdom of a lifetime.”

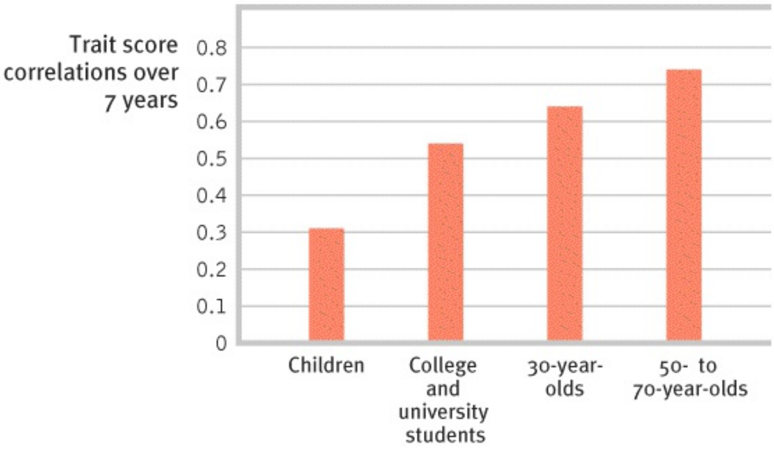

Figure 57.3
Myers/DeWall, *Myers’ Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from Roberts & DelVecchio, 2000.

Figure 57.3 Personality stability

With age, personality traits become more stable, as reflected in the stronger correlation of trait scores with follow-up scores 7 years later.

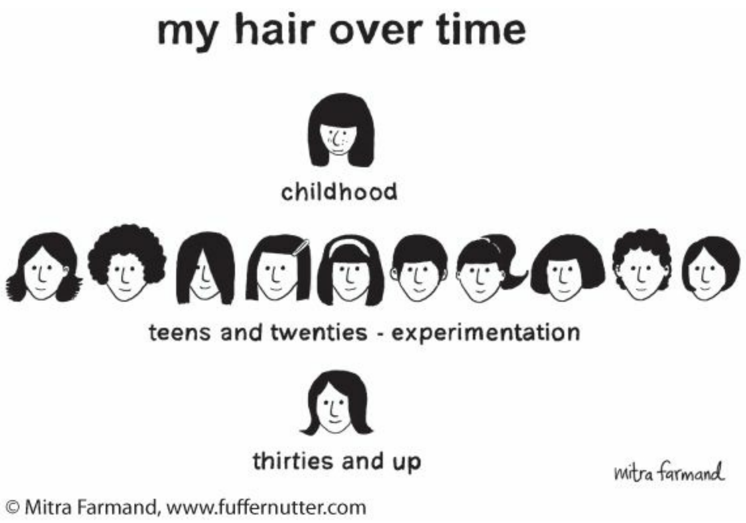
So most people—including most psychologists—would probably presume the stability of personality traits. Moreover, our traits are socially significant. They influence our health, our thinking, and our job choices and performance (Hogan, 1998; Jackson et al., 2012; Sutin et al., 2011).

Studies that follow lives through time show that personality traits rival socioeconomic status and cognitive ability as predictors of mortality, divorce, and occupational attainment (Roberts et al., 2007).

FYI

Change and consistency can coexist. If all people were to become somewhat less shy with age, there would be personality change, but also relative stability and predictability.

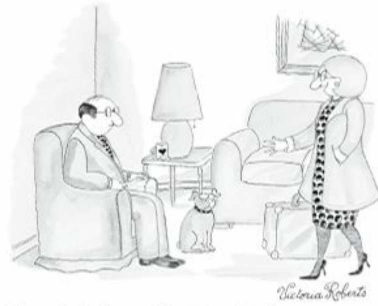
Although our personality *traits* may be both stable and potent, the consistency of our specific *behaviors* from one situation to the next is another matter. What relationship would you expect to find between being conscientious in one situation (say, showing up for class on time) and being conscientious in another (say, avoiding unhealthy foods)? If you've noticed how outgoing you are in some situations and how reserved you are in others, perhaps you said, "Very little." That's what researchers have found—only a small correlation (Mischel, 1968; Sherman et al., 2015). This inconsistency in behaviors also makes personality test scores weak predictors of behaviors. People's scores on an extraversion test, for example, do not neatly predict how sociable they actually will be on any given occasion.



© Mitra Farmand, www.fuffernutter.com

It's not just personality that stabilizes with age.

If we remember such results, we will be more cautious about labeling and pigeonholing individuals (Mischel, 1968). Years in advance, science can tell us the phase of the Moon for any given date. A day in advance, meteorologists can often predict the weather. But we are much further from being able to predict how *you* will feel and act tomorrow.



Victoria Roberts The New Yorker Collection/The Cartoon Bank

"I'm going to France—I'm a different person in France."

However, people's *average* outgoingness, happiness, or carelessness over many situations is predictable (Epstein, 1983a,b). People who know someone well, therefore, generally agree when rating that person's shyness or agreeableness (Jackson et al., 2015; Kenrick & Funder, 1988). By collecting snippets of people's daily experience via body-worn recording devices, Matthias Mehl and his colleagues (2006) confirmed that extraverts really do talk more. (I [DM] have repeatedly vowed to cut back on my jabbering and joking during my noontime pickup basketball games with friends. Alas, moments later, the irrepressible chatterbox inevitably reoccupies my body. And I [ND] have a similar experience each time I try to stay quiet in taxis. Somehow, I always end up chatting with the driver!) As our best friends can verify, we do have persistent (genetically influenced) personality traits. And our personality traits get expressed in our:

- *music preferences.* Your playlist reveals something of your personality. Classical, jazz, blues, and folk music lovers tend to be open to experience. Extraverts tend to prefer upbeat and energetic music. Country, pop, and religious music lovers tend to be cheerful, outgoing, and conscientious (Langmeyer et al., 2012; Rentfrow & Gosling, 2003, 2006). On first meeting, students often disclose their music preferences to one another; in doing so, they are swapping information about their personalities.

- *written communications.* If you have ever felt you could detect someone's personality from their writing voice, you are right!! What a cool finding!!! ☺ People's writings—even their brief tweets and Facebook posts—often express their extraversion, self-esteem, and agreeableness (Orehek & Human, 2017; Park et al., 2015; Pennebaker, 2011). "Off to meet a friend. Woohoo!!!" posted one Facebook user who had scored high on extraversion (Kern et al., 2014). Extraverts also use more adjectives.
- *online and personal spaces.* Are online profiles, websites, and avatars also a canvas for self-expression? Or are they an opportunity for people to present themselves in false or misleading ways? It's more the former (Back et al., 2010; Gosling et al., 2007; Marcus et al., 2006). People who seemed most likable on their Facebook or Twitter pages also seemed most likable in person (Qiu et al., 2012; Weisbuch et al., 2009). Even mere photos, with their associated clothes, expressions, and postures, can give clues to personality (Naumann et al., 2009). Our living and working spaces also help us express our identity. They all offer clues to our extraversion, agreeableness, conscientiousness, and openness (Back et al., 2010; Fong & Mar, 2015; Gosling, 2008).

In unfamiliar, formal situations—perhaps as a guest in the home of a person from another culture—our traits remain hidden as we carefully attend to social cues. In familiar, informal situations—just hanging out with friends—we feel less constrained, allowing our traits to emerge (Buss, 1989). In these informal situations, our expressive styles—our animation, manner of speaking, and gestures—are impressively consistent. Viewing "thin slices" of someone's behavior—such as seeing a photo for a mere fraction of a second, or seeing several 2-second video clips of a teacher in action—can tell us a lot about the person's basic personality traits (Ambady, 2010; Tackett et al., 2016).

Joe Baraban/Alamy

Room with a cue Even at “zero acquaintance,” people can catch a glimpse of others’ personality from looking at their online and personal spaces. So, what’s your read on this person?

Some people are naturally expressive (and therefore talented at pantomime and charades); others are less expressive (and therefore better poker players). To evaluate people’s voluntary control over their expressiveness, researchers asked people to *act* as expressive or inhibited as possible while stating opinions (DePaulo et al., 1992). Their remarkable findings: Inexpressive people, even when feigning expressiveness, were less expressive than expressive people acting naturally. Similarly, expressive people, even when trying to seem inhibited, were less inhibited than inexpressive people acting naturally. It’s hard to be someone you’re not, or not to be who you are.

To sum up, we can say that at any moment the immediate situation powerfully influences a person’s behavior. Social psychologists have learned that this is especially so when a “strong situation” makes clear demands (Cooper & Withey, 2009). We can better predict drivers’ behavior at traffic lights from knowing the color of the lights than from knowing the drivers’ personalities. Thus, teachers may perceive certain students as subdued (based on their classroom behavior), but friends may perceive them as pretty wild (based on their party behavior). Averaging our behavior across many occasions does, however, reveal distinct personality traits. Traits exist. We differ. And our differences matter.

✓ Check Your Understanding

Ask Yourself

- How do think your own personality traits shine through in your music preferences, communication style, and online and personal spaces? Can you recall a recent time in which the situation you were in definitely constrained your usual behavior?

Test Yourself

- How well do personality test scores predict our behavior? Explain.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 57 REVIEW

57-1 How do psychologists use traits to describe personality?

- *Trait* theorists see personality as a stable and enduring pattern of behavior. They have been more interested in trying to describe our differences than in explaining them.
- Using factor analysis, they identify clusters of behavior tendencies that occur together. Genetic predispositions influence many traits.

57-2 What are some common misunderstandings about introversion?

- Western cultures prize extraversion, but introverts have different, equally important skills. Introversion does not equal shyness, and extraverts don't always outperform introverts as leaders or in sales success. Introverts often experience great achievement; many introverts prosper.

57-3 What are *personality inventories*, and what are their strengths and weaknesses as trait-assessment tools?

- *Personality inventories* (such as the *MMPI*) are questionnaires on which people respond to items designed to gauge a wide range of feelings and behaviors.
- Test items are *empirically derived*, and the tests are objectively scored. But people can fake their answers to create a good impression; objectivity does not guarantee validity.

57-4 Which traits seem to provide the most useful information about personality variation?

- The Big Five personality factors—conscientiousness, agreeableness, neuroticism, openness, and extraversion (CANOE)—currently offer the clearest picture of personality.

- These factors are stable and appear to be found in all cultures. Many genes, each having small effects, combine to influence our traits, and heritability generally runs about 40 percent for each dimension.

57-5 Does research support the consistency of personality traits over time and across situations?

- A person’s average traits persist over time and are predictable over many different situations. But traits cannot predict behavior in any one particular situation.

Multiple-Choice Questions

1. Which of the following is the best term or phrase for a characteristic pattern of behavior or a disposition to feel and act?

a. Myers-Briggs indicator
b. Factor analysis
c. Introversion
d. Extraversion
e. Trait

2. Jayne refuses to cheat on an exam that many of her friends have shown her copies of. Jayne would rank high on the Big Five trait of

a. conscientiousness.
b. agreeableness.
c. openness.
d. extraversion.
e. neuroticism.

3. Which of the following is best described along a continuum ranging from ruthless and suspicious to helpful and trusting?

a. Conscientiousness

b. Agreeableness
c. Openness
d. Extraversion
e. Neuroticism

4. Which of the following is true based on “Big Five” personality traits research?

a. Highly conscientious people are likely to be evening people or “night owls.”
b. Highly conscientious people get poor grades.
c. Married partners scoring the same on agreeableness are more likely to experience marital dissatisfaction.
d. Introverts are more likely to prefer communicating through email instead of in person.
e. Neuroticism predicts the use of positive-emotion words in text messages.

Practice FRQs

1. Explain one weakness and one strength of the Minnesota Multiphasic Personality Inventory (MMPI).

Answer

1 point: One point for any strength (for example, the MMPI is empirically derived, assesses several traits at once, or is easily scored). Page 599

1 point: One point for any weakness (for example, the MMPI test-taker might not answer honestly, or validity is not guaranteed). Page 599

2. Gustavo has been rated highly on each of the following traits:

- Openness
- Agreeableness
- Extraversion

Provide an example of a behavior for each of the three traits that would indicate that he was correctly rated.

Module 58 Social-Cognitive Theories

LEARNING TARGETS

- 58-1 Describe how social-cognitive theorists view personality development and how they explore behavior.
- 58-2 Discuss the criticisms social-cognitive theorists have faced.

58-1 How do social-cognitive theorists view personality development, and how do they explore behavior?

The **social-cognitive perspective** on personality that Albert Bandura (1986, 2006, 2008) proposed emphasizes the interaction of our traits with our situations. Much as nature and nurture always work together, so do individuals and their situations.

social-cognitive perspective
views behavior as influenced by the interaction between people’s traits (including their thinking) and their social context.

Those who take the **behavioral approach** to personality development emphasize the effects of learning. We are conditioned to repeat certain behaviors, and we learn by observing and imitating others. For example, a child with a very controlling parent may learn to follow orders rather than think independently, and may exhibit a more timid personality.

behavioral approach

focuses on the effects of learning on our personality development.

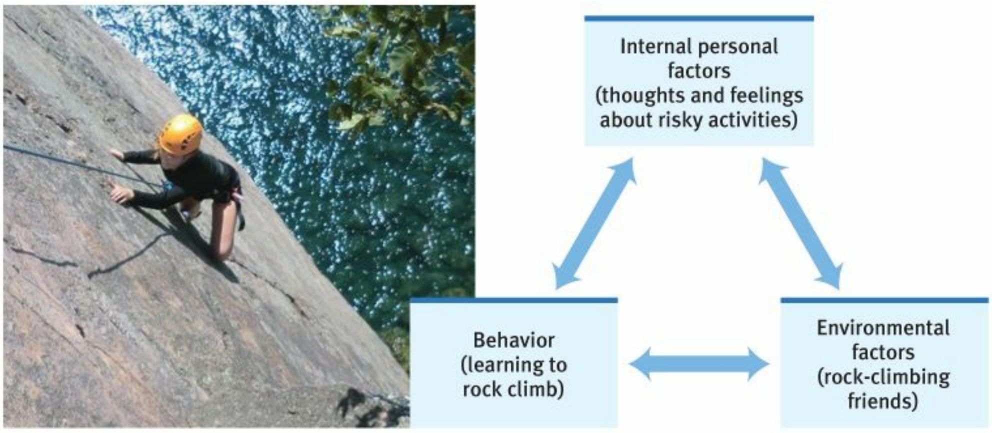
Social-cognitive theorists do consider the behavioral perspective, believing that we learn many of our behaviors either through conditioning or by observing and imitating others. (That’s the “social” part.) They also emphasize the importance of mental processes: What we *think* about a situation affects our resulting behavior. (That’s the “cognitive” part.) Instead of focusing solely on how our environment *controls* us, as behaviorists do, social-cognitive theorists focus on how we and our environment *interact:* How do we interpret and respond to external events? How do our schemas, our memories, and our expectations influence our behavior patterns?

Reciprocal Influences

Bandura (1986, 2006) views the person-environment interaction as **reciprocal determinism**. “Behavior, internal personal factors, and environmental influences,” he said, “all operate as interlocking determinants of each other” (**Figure 58.1**). We can see this interaction in people’s relationships. For example, Rosa’s past romantic experience (her behaviors) influence her romantic attitudes (internal factor), which affect how she now responds to Ryan (environmental factor).

reciprocal determinism

the interacting influences of behavior, internal cognition, and environment.



Internal personal factors (thoughts and feelings about risky activities)
Behavior (learning to rock climb)
Environmental factors (rock-climbing friends)

Figure 58.1
Myers/DeWall, *Myers’ Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Courtesy of Joslyn Brugh

Figure 58.1 **Reciprocal determinism**

The social-cognitive perspective proposes that our personalities are shaped by the interaction of our personal traits (including our thoughts and feelings), our environment, and our behaviors.

Flip It Video: Reciprocal Determinism

Consider three specific ways in which individuals and environments interact:

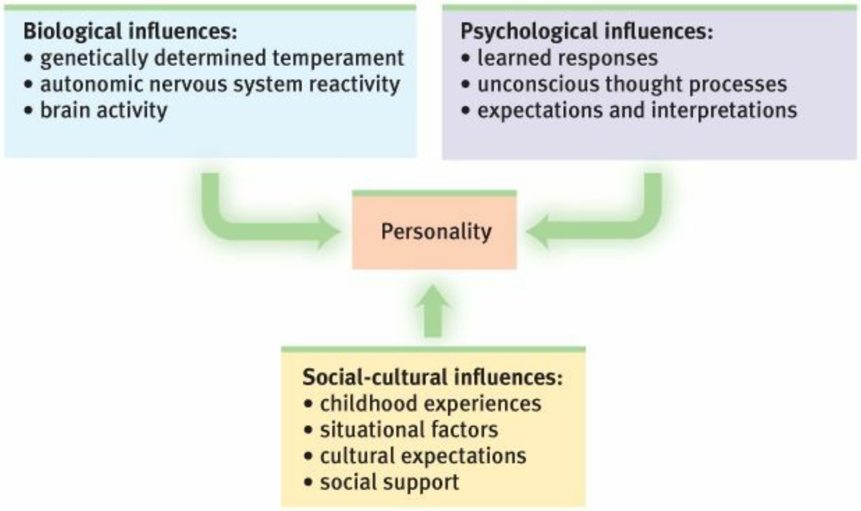
1. ***Different people choose different environments.*** The reading you do,

the shows you watch, the music you listen to, the friends you associate with—all are part of an environment you participated in choosing, based partly on your disposition (Funder, 2009; Ickes et al., 1997). People with inflated self-esteem choose to post frequent selfies in online environments, where they can receive the public attention and praise they crave. This leads to even greater self-love (Halpern et al., 2016). We choose our environment and it then shapes us.

2. ***Our personalities shape how we interpret and react to events.*** Anxious people tend to attend and react strongly to relationship threats (Campbell & Marshall, 2011). If we perceive the world as threatening, we will watch for threats and be prepared to defend ourselves.
3. ***Our personalities help create situations to which we react.*** How we view and treat people influences how they then treat us. If we expect that others will not like us, our bragging and other efforts to seek their approval might cause them to reject us (Scopelliti et al., 2015).

In addition to the interaction of internal personal factors, the environment, and our behaviors, we also experience *gene-environment interaction* (Module 14). Our genetically influenced traits evoke certain responses from others, which may nudge us in one direction or another. In one classic study, those with the interacting factors of (1) having a specific gene associated with aggression, plus (2) being raised in a difficult environment were most likely to demonstrate adult antisocial behavior (Caspi et al., 2002).

In such ways, we are both the products and the architects of our environments: *Behavior emerges from the interplay of external and internal influences.* Boiling water turns an egg hard and a potato soft. A threatening environment turns one person into a hero, another into a scoundrel. Extraverts enjoy greater well-being in an extraverted culture than in an introverted one (Fulmer et al., 2010). *At every moment,* our behavior is influenced by our biology, our social and cultural experiences, and our cognition and dispositions (**Figure 58.2**).



Biological influences:
• genetically determined temperament
• autonomic nervous system reactivity
• brain activity
Psychological influences:
• learned responses
• unconscious thought processes
• expectations and interpretations
Personality
Social-cultural influences:
• childhood experiences
• situational factors
• cultural expectations
• social support

Figure 58.2

Figure 58.2 The biopsychosocial approach to the study of personality

As with other psychological phenomena, personality is fruitfully studied at multiple levels.

Assessing Behavior in Situations

To predict behavior, social-cognitive psychologists often observe behavior in realistic situations. One ambitious example was the U.S. Army's World War II strategy for assessing candidates for spy missions. Rather than using paper-and-pencil tests, Army psychologists subjected the candidates to simulated undercover conditions. They tested their ability to handle stress, solve problems, maintain leadership, and withstand intense interrogation without blowing their cover. Although time-consuming and expensive, this assessment of behavior in a realistic situation helped predict later success on actual spy missions (OSS Assessment Staff, 1948).

Military and educational organizations and many Fortune 500 companies have adopted assessment center strategies (Bray & Byham, 1991, 1997; Eurich et al., 2009). AT&T has observed prospective managers doing simulated managerial work. Student teachers are observed and evaluated several times during the term they spend in your school. Many colleges assess nursing students' potential by observing their clinical work, and they assess potential faculty members' teaching abilities by observing them teach. Most American cities with populations of 50,000 or more have used assessment centers in evaluating police officers and firefighters (Lowry, 1997).

These procedures exploit the principle that the best means of predicting behavior is neither a personality test nor an interviewer's intuition. Rather, *the best predictor of future behavior is the person's past behavior patterns in similar situations* (Lyons et al., 2011; Mischel, 1981; Schmidt & Hunter, 1998). As long as the situation and the person remain much the same, the best predictor of future job performance is past job performance; the best predictor of future grades is past grades; the best predictor of future aggressiveness is past aggressiveness. If you can't check the person's past behavior, the next best thing is to create an assessment situation that simulates the task so you can see how the person handles it (Lievens et al., 2009; Meriac et al., 2008).

FYI

A *New York Times* analysis of 100 rampage murders over the last half-century revealed that 55 of the killers had regularly exploded in anger and 63 had threatened violence (Goodstein & Glaberson, 2000). Most didn’t, out of the blue, “just snap.”

Evaluating Social-Cognitive Theories

58-2 What criticisms have social-cognitive theorists faced?

Social-cognitive theories of personality sensitize researchers to how situations affect, and are affected by, individuals. More than other personality theories (see **Table 58.1**), they build from psychological research on learning and cognition.

TABLE 58.1 Comparing the Major Personality Theories

Personality Theory	Key Proponents	Assumptions	View of Personality
Psychoanalytic	Freud	Emotional disorders spring from unconscious dynamics, such as unresolved sexual and other childhood conflicts, and fixation at various developmental stages. Defense mechanisms fend off anxiety.	Personality consists of pleasure-seeking impulses (the id), a reality-oriented executive (the ego), and an internalized set of ideals (the superego).
Psychodynamic	Adler, Horney, Jung	The unconscious and conscious minds interact. Childhood experiences and defense mechanisms are important.	The dynamic interplay of conscious and unconscious motives and conflicts shapes our personality.
Humanistic	Rogers, Maslow	Rather than examining the struggles of sick people, it's better to focus on the ways healthy people may strive for self-	If our basic human needs are met, we will strive toward self-actualization. In a climate of unconditional positive regard, we

		realization.	can develop self-awareness and a more realistic and positive self-concept.
Trait	Allport; Eysenck, H.; Eysenck, S.; McCrae; Costa	We have certain stable and enduring characteristics, influenced by genetic predispositions.	Scientific study of traits has isolated important dimensions of personality, such as the Big Five traits (conscientiousness, agreeableness, neuroticism, openness, and extraversion).
Social-Cognitive	Bandura	Our traits interact with the social context to produce our behaviors—a phenomenon called *reciprocal determinism.*	Conditioning and observational learning interact with cognition to create behavior patterns. Our behavior in one situation is best predicted by considering our past behavior in similar situations.

AP® EXAM TIP

Tables 58.1 and 58.2 summarize a whole unit's worth of information. Review research methods and study the tables well to be clear on the distinctions separating the major approaches to personality.

Critics charge that social-cognitive theories focus so much on the situation that they fail to appreciate the person's inner traits. Where is the person in this view of personality, ask the dissenters, and where are human emotions? True, the situation does guide our behavior. But, say the critics, in many instances our unconscious motives, our emotions, and our pervasive traits shine through. Personality traits have been shown to predict behavior at work, in love, and at play. Our biologically influenced traits really do matter. Consider Percy Ray Pridgen and Charles Gill. Each faced the same situation: They had jointly won a $90 million lottery jackpot (Harriston, 1993). When Pridgen learned of the winning numbers, he began trembling uncontrollably, huddled with a friend behind a bathroom door while confirming the win, and then sobbed. When Gill heard the news, he told his wife and went to sleep.

* * *

As we have seen, researchers investigate personality using various methods that serve differing purposes. For a synopsis and comparison of these methods, see **Table 58.2**.

TABLE 58.2 Comparing Research Methods to Investigate Personality

Research Method	**Description**	**Perspectives Incorporating This Method**	**Benefits**	**Weakn**
Case study	In-depth study of one individual.	Psychoanalytic, humanistic	Less expensive than other methods.	May not generaliz the large populatio
Survey	Systematic questioning of a random sample of the population.	Trait, social-cognitive	Results tend to be reliable and can be generalized to the larger population.	May be expensiv correlatic findings.

✓ Check Your Understanding

Ask Yourself

- Can you think of a recent situation in which your personality led you to react differently than did some classmates who experienced the same event?

Test Yourself

- Albert Bandura proposed the _______________-_______________ perspective on personality, which emphasizes the interaction of people with their environment. To describe the interacting influences of behavior, thoughts, and environment, he used the term ________________ ________________.

- What is the best way to predict a person’s future behavior?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 58 REVIEW

58-1 How do social-cognitive theorists view personality development, and how do they explore behavior?

- Albert Bandura first proposed the *social-cognitive perspective*, which views personality as the product of the interaction between a person’s traits (including thinking) and the situation—the social world around us.
- The *behavioral approach* contributes an understanding that our personality development is affected by learned responses.
- Social-cognitive researchers apply principles of learning, as well as cognition and social behavior, to personality.
- *Reciprocal determinism* describes the interaction and mutual influence of behavior, internal personal factors, and environmental factors.
- Assessment situations involving simulated conditions exploit the principle that the best predictor of future behavior is a person’s behavior patterns in similar situations.

58-2 What criticisms have social-cognitive theorists faced?

- Social-cognitive theories of personality build on well-established concepts of learning and cognition, and sensitize researchers to how situations affect, and are affected by, individuals.
- Social-cognitive theorists have been faulted for underemphasizing the importance of unconscious motives, emotions, and biologically influenced traits.

Multiple-Choice Questions

1. Who of the following is considered the leading advocate of personality’s social-cognitive approach?

a. Gordon Allport

   b. Carl Jung
   c. Karen Horney
   d. Carl Rogers
   e. Albert Bandura

2. The way we explain negative and positive events is called

   a. personal control.
   b. reciprocal determinism.
   c. self-efficacy.
   d. attribution.
   e. situational assessment.

3. Which of the following is an example of an assessment likely to be used by a social-cognitive psychologist?

   a. A student teacher is formally observed and evaluated in the classroom.
   b. A person applying for a managerial position takes the Myers-Briggs Type Indicator.
   c. A defendant in a criminal case is interviewed by a court-appointed psychologist.
   d. In a pre-marriage counseling session, a young couple responds to ambiguous inkblots.
   e. A depressed young man is asked by his therapist to relax on a couch and talk about whatever comes to mind.

Practice FRQs

1. Heidi is an avid reader. Explain how Heidi’s desire to read may be supported by the following elements of reciprocal determinism:

- Internal factors
- Environmental factors
- Behavioral factors

Answer

1 point: Internal factors that cause Heidi to enjoy reading might include her verbal aptitude or her curiosity. Page 606

1 point: Environmental factors that cause Heidi to enjoy reading might include having grown up in a family where reading was valued and encouraged. Page 606

1 point: Behavioral factors that cause Heidi to enjoy reading might include the pleasure she gets from reading, which further reinforces her desire to read. Page 606

2. Explain the main criticism of social-cognitive theories and one main support for this approach.

(2 points)

Module 59 Exploring the Self

LEARNING TARGETS

- 59-1 Explain why psychology has generated so much research on the self, and discuss the importance of self-esteem to our well-being.
- 59-2 Describe how excessive optimism, blindness to one's own incompetence, and self-serving bias reveal the costs of self-esteem, and explain how defensive and secure self-esteem differ.
- 59-3 Discuss how individualist and collectivist cultures differ in their values and goals.

59-1 Why has psychology generated so much research on the self? How important is self-esteem to our well-being?

Our personality feeds our sense of self. Asked to consider "Who I am," people draw on their distinctive and enduring ways of thinking, feeling, and acting. Psychology's concern with our sense of self dates back at least to William James, who devoted more than 100 pages of his 1890 *Principles of Psychology* to the topic. By 1943, Gordon Allport lamented that the self had become "lost to view." Although humanistic psychology's later emphasis on the self did not instigate much scientific research, it did help renew the concept of self and keep it alive. Now, more than a century after James, the self is one of Western psychology's most vigorously researched topics. Every year, new studies galore appear on self-esteem, self-disclosure, self-awareness, self-schemas, self-monitoring, and more. Even neuroscientists have searched for the self, by identifying a central frontal lobe region that activates when people respond to self-reflective questions about their traits and dispositions (Damasio, 2010; Mitchell, 2009; Pauly et al., 2013). The **self**, as organizer of our thoughts, feelings, and actions, occupies the center of personality.

self

in contemporary psychology, assumed to be the center of personality, the organizer of our thoughts, feelings, and actions.

One example of thinking about self is the concept of *possible selves* (Markus & Nurius, 1986; Rathbone et al., 2016). Your possible selves include your visions of the self you dream of becoming—the rich self, the successful self, the loved and admired self. Your possible selves also include the self you fear becoming—the unemployed self, the academically failed self, the lonely and unpopular self. Possible selves motivate us to lay out specific goals that direct our energy effectively and efficiently (Landau, M. J. et al., 2014). Middle school students whose families struggle financially are more likely to earn high grades if they have a clear vision of themselves succeeding in school (Duckworth et al., 2013). Dreams often do give birth to achievements.

Neil Collins/Alamy

Possible selves By giving them a chance to try out many possible selves, pretend games offer children important opportunities to develop emotionally, socially, and cognitively. This young girl may or may not grow up to be a physician, but playing various adult roles will expand her vision of what she might become.

> “*The first step to better times is to imagine them.*”
>
> *Chinese fortune cookie*

Our self-focused perspective may motivate us, but it can also lead us to presume too readily that others are noticing and evaluating us. One researcher demonstrated this **spotlight effect** by having Cornell University students don T-shirts featuring soft-rock singer Barry Manilow before entering a room with other students (Gilovich, 1996). Feeling self-conscious, the T-shirt wearers guessed that nearly half their peers would take note of the shirt as they walked in. In reality, only 23 percent did. The point to remember: *We stand out less than we imagine,* even with dorky clothes and bad hair, and even after a blunder like setting off a library alarm (Gilovich & Savitsky, 1999; Savitsky et al., 2001).

spotlight effect

overestimating others’ noticing and evaluating our appearance, performance, and blunders (as if we presume a spotlight shines on us).

To turn down the spotlight’s brightness, we can use two strategies. The first is simply to know and remember the spotlight effect. Public speakers perform better if they understand that their natural nervousness is hardly noticeable (Savitsky & Gilovich, 2003). The second is to take the audience’s perspective. When we imagine audience members empathizing with our situation, we tend to expect we will not be judged as harshly (Epley et al., 2002).

Trinity Mirror/Mirrorpix/Alamy Tim Large /Shutterstock

The Benefits of Self-Esteem

Self-esteem—our feelings of high or low self-worth—matters. So does **self-efficacy**, our sense of competence on a task (Bandura, 1977). (A student might feel high self-efficacy in a math class yet low overall self-esteem.) People who feel good about themselves (who strongly agree with self-affirming questionnaire statements, such as "I am fun to be with") have fewer sleepless nights. They succumb less easily to pressures to conform. They make more positive Facebook posts, causing others to like them more (Forest & Wood, 2012). They are more persistent at difficult tasks. They feel less shy, anxious, and lonely, and are just plain happier (Greenberg, 2008; Orth & Robins, 2014; Swann et al., 2007). If feeling bad, they think they deserve better and thus make more effort to repair their mood (Wood et al., 2009). Our self-esteem grows from venturesome experiences and achievement, and therefore changes as we age (Hutteman et al., 2015). In one study of nearly 1 million people across 48 nations, self-esteem increased from adolescence to middle adulthood (Bleidorn et al., 2016).

self-esteem

one's feelings of high or low self-worth.

self-efficacy

one's sense of competence and effectiveness.

But is high self-esteem the horse or the cart? Is it really "the armor that protects kids" from life's problems (McKay, 2000)? Some psychologists have their doubts (Baumeister, 2006; Seligman, 1994, 2002). Children's academic self-efficacy—their confidence that they can do well in a subject—predicts school achievement. But general self-image does not (Marsh & Craven, 2006; Swann et al., 2007; Trautwein et al., 2006). Maybe self-esteem simply reflects reality. Maybe it's a side effect of meeting challenges and surmounting difficulties. Maybe self-esteem is a gauge that reports the state of our relationships with others (Reitz et al., 2016). If so, isn’t pushing the gauge artificially higher with empty compliments much like forcing a car’s low fuel gauge to display “full”?

AP® EXAM TIP

Note the difference between *self-esteem* and *self-efficacy*. Although your feeling of self-worth might be related to your beliefs about how competent you are, they are not the same thing.

If feeling good *follows* doing well, then giving praise in the absence of good performance may actually harm people. After receiving weekly self-esteem-boosting messages, struggling students earned *lower*-than-expected grades (Forsyth et al., 2007). Other research showed that giving people random rewards hurt their productivity. Martin Seligman (2012) reported that “when good things occurred that weren’t earned, like nickels coming out of slot machines, it did not increase people’s well-being. It produced helplessness. People gave up and became passive.”

> “*When kids increase in self-control, their grades go up later. But when kids increase their self-esteem, there is no effect on their grades.*”
>
> *Angela Duckworth,* In Character interview, *2009*

There is, however, an important *effect* of low self-esteem. When researchers temporarily deflated people’s self-image (by telling them they did poorly on an aptitude test or by disparaging their personality), those participants became more likely to disparage others or to express heightened racial prejudice (van Dijk et al., 2011; vanDellen et al., 2011; Ybarra, 1999). Self-image threat even increases unconscious racial bias (Allen & Sherman, 2011). Those who are negative about themselves have also tended to be oversensitive and judgmental (Baumgardner et al., 1989; Pelham, 1993). Self-esteem threats also lead people to spend more time with their online profiles—safe havens in which to rebuild their self-worth (Toma & Hancock, 2013). Such findings are consistent with humanistic psychology’s ideas about the benefits of a healthy self-image. Accept yourself and you’ll find it easier to accept others. Disparage yourself and you will be prone to the floccinaucinihilipilification[1] of others. Said more simply, some “love their neighbors as themselves”; others loathe their neighbors as themselves. People who are down on themselves tend to be down on others.

The Costs of Self-Esteem

59-2 How do excessive optimism, blindness to one’s own incompetence, and self-serving bias reveal the costs of self-esteem, and how do defensive and secure self-esteem differ?

Excessive Optimism

Positive thinking in the face of adversity can pay dividends, but so, too, can a dash of realism (Schneider, 2001). Realistic anxiety over possible future failures can fuel energetic efforts to avoid the dreaded fate (Goodhart, 1986; Norem, 2001; Showers, 1992). Concerned about failing an upcoming test, students may study thoroughly and outperform their equally able but more confident peers. Asian-American students have expressed somewhat greater pessimism than their European-American counterparts, which may help explain their often impressive academic achievements (Chang, 2001). Success requires enough optimism to provide hope and enough pessimism to prevent complacency. We want our airline pilots to be mindful of worst-possible outcomes.

Excessive optimism can blind us to real risks (Tenney et al., 2015). More than 1000 studies have shown how our natural positive thinking bias can promote “an unrealistic optimism about future life events” (Shepperd et al., 2015; Weinstein, 1980). When 56 percent of twelfth graders believed they would earn a graduate degree—though only 9 percent were likely to do so—that was unrealistic optimism (Reynolds et al., 2006). When most students perceived themselves as more likely than their classmates to get a high-paying job and own a nice home, and less likely to have a heart attack or get cancer, that, too, was unrealistic optimism (Waters et al., 2011). If overconfident of our ability to control an impulse such as the urge to smoke, we are more likely to expose ourselves to temptations—and to fail (Nordgren et al., 2009). Blind optimism can be self-defeating, as we can see in those who optimistically deny the addictive toxicity of smoking or venture into ill-fated relationships.

Our natural positive thinking bias does seem to vanish, however, when we are bracing ourselves for feedback, such as test results (Carroll et al., 2006). In one analysis of 71 studies, optimism morphed toward pessimism shortly before the moment of truth (Sweeny & Krizan, 2013). Positive illusions also vanish after a traumatic personal experience—as they did for victims of a catastrophic California earthquake, who had to give up their illusions of being less vulnerable than others to earthquakes (Helweg-Larsen, 1999).

Blindness to One’s Own Incompetence

Ironically, people often are most overconfident when most incompetent. That, said Justin Kruger and David Dunning (1999), is because it often takes competence to recognize competence. They found that most students scoring at the low end of grammar and logic tests believed they had scored in the top half. If you do not know what is logical, you may be unaware of your illogic. This “ignorance of one’s own incompetence” phenomenon—now called the *Dunning-Kruger effect*—can produce overconfidence among political leaders. It also has a parallel among those of us with hearing loss, as I [DM] can confirm. Because we are unaware of what we don’t hear, we may overestimate our hearing. If I fail to hear my friend calling my name, the friend notices my inattention. But for me it’s a nonevent. I hear what I hear—which, to me, seems pretty normal.

The difficulty in recognizing one’s own incompetence helps explain why so many low-scoring students are dumbfounded after blowing a big test. If you don’t know all the Scrabble word possibilities you’ve overlooked, you may feel pretty smart—until they are pointed out. Our ignorance of what we don’t know sustains our self-confidence, leading us to make the same mistakes (Williams et al., 2013).

To judge one’s competence and predict one’s future performance, it pays to invite others’ assessments (Dunning, 2006; Grossmann & Kross, 2014). Based on studies in which both individuals and their acquaintances predict their future, we can hazard some advice: Ask your peers for their candid prediction. If you’re in love and want to predict whether it will last, don’t listen to your heart—ask your friends.

Self-Serving Bias

Imagine dashing to class, hoping not to miss the first few minutes. But you arrive five minutes late, huffing and puffing. As you sink into your seat, what sorts of thoughts go through your mind? Do you go through a negative door, thinking “I’m such a loser”? Or do you go through a positive door, telling yourself “I really tried to get here on time”?

Personality psychologists have found that most people choose the second door, which leads to positive self-thoughts. We have a good reputation with ourselves. We show a **self-serving bias**—a readiness to perceive ourselves favorably (Myers, 2010). Consider:

self-serving bias

a readiness to perceive oneself favorably.

People accept more responsibility for good deeds than for bad, and for successes than for failures. Athletes often privately credit their victories to their own prowess, and their losses to bad breaks, lousy officiating, or the other team’s exceptional performance. Most students who receive poor test grades criticize the test or the teacher, not themselves. Drivers filling out insurance forms have explained their accidents in such words as “A pedestrian hit me and went under my car.” The question “What have I done to deserve this?” is one we usually ask of our troubles, not our successes. Although a self-serving bias can lead us to avoid uncomfortable truths, it can also motivate us to approach difficult tasks with confidence instead of despair (Tomaka et al., 1992; von Hippel & Trivers, 2011).

> “*I never blame myself when I’m not hitting. I just blame the bat and if it keeps up, I change bats.*”
>
> *Baseball great Yogi Berra*

Most people see themselves as better than average. Compared with most other people, how moral are you? How easy to get along with? Where would you rank yourself, from the 1st to the 99th percentile? Most people put themselves well above the 50th percentile. This better-than-average effect appears for nearly any subjectively assessed and socially desirable behavior. Some examples:

- In U.S. surveys, most business executives say they are more ethical than their average counterpart. In several studies, 90 percent of business managers and more than 90 percent of college professors also rated their performance as superior to that of their average peer.
- In Australia, 86 percent of people rate their job performance as above average, and only 1 percent as below average.
- In the U.S. National Survey of Families and Households, 49 percent of men said they provided half or more of the child care, though only 31 percent of their wives or partners saw things that way (Galinsky et al., 2008).

Andrews McMeel Syndication

Self-serving bias reflects both an overestimation of the self and a desire to maintain a positive self-view (Brown, 2012; Epley & Dunning, 2000). This motivation to see ourselves positively is weaker in Asia, where people tend to value modesty (Church et al., 2014; Falk, C. F. et al., 2009). Yet self-serving biases have been observed worldwide: In every one of 53 countries surveyed, people expressed self-esteem above the midpoint of the most widely used scale (Schmitt & Allik, 2005). The world, it seems, is Garrison Keillor’s Lake Wobegon writ large—a place where “all the women are strong, all the men are good-looking, and all the children are above average."

> “*If you are like most people, then like most people, you don’t know you’re like most people. Science has given us a lot of facts about the average person, and one of the most reliable of these facts is the average person doesn’t see herself as average.*”
>
> *Daniel Gilbert*, Stumbling on Happiness, *2006*

Finding their self-esteem threatened, people with large egos may react violently. Researchers Brad Bushman and Roy Baumeister (1998; Bushman et al., 2009) had undergraduate volunteers write a brief essay, in response to which another supposed student gave them either praise ("Great essay!") or stinging criticism ("One of the worst essays I have read!"). The essay writers were then allowed to lash out at their evaluators by blasting them with unpleasant noise. Can you anticipate the result?

After criticism, those with inflated self-esteem were "exceptionally aggressive." They delivered a three times greater noise blast than did those with normal self-esteem. Over 80 follow-up studies have replicated the dangerous effect of **narcissism** (excessive self-love and self-focus) on aggression (Rasmussen, 2016). Researchers have concluded that "conceited, self-important individuals turn nasty toward those who puncture their bubbles of self-love" (Baumeister, 2001).

narcissism

excessive self-love and self-absorption.

After tracking self-importance across several decades, psychologist Jean Twenge (2014; Twenge & Foster, 2010) reported that what she called *Generation Me*—born in the 1980s and early 1990s—expressed more narcissism (by agreeing more often with statements such as, "If I ruled the world, it would be a better place," or "I think I am a special person"). Why does a rise in narcissism matter? Narcissists tend to be materialistic, desire fame, have inflated expectations, hook up more often without commitment, and gamble and cheat more—all of which have been increasing as narcissism has increased. Narcissistic people (more often men) forgive others less, take a game-playing approach to their romantic relationships, and engage in sexually forceful behavior (Blinkhorn et al., 2015; Bushman et al., 2003; Grijalva et al., 2015). They crave adulation, are active on social media, and often become enraged when criticized (Geukes et al., 2016; Krizan & Johar, 2015; McCain & Campbell, 2017). Many had parents who told them they were superior to others (Brummelman et al., 2015). They typically make good first impressions, which wane over time as their arrogance and bragging gets old (Czarna et al., 2016; Leckelt et al., 2015). Reality television stars are especially narcissistic (Rubinstein, 2016; Young & Pinsky, 2006).

> “*The enthusiastic claims of the self-esteem movement mostly range from fantasy to hogwash. The effects of self-esteem are small, limited, and not all good.*”
>
> *Roy Baumeister (1996)*

Despite the demonstrated perils of pride, many people object that the idea of self-serving bias overlooks those who feel worthless and unlovable. If self-serving bias prevails, why do so many people disparage themselves? For four reasons: (1) Sometimes self-directed put-downs are *subtly strategic*—they elicit reassuring strokes. Saying “No one likes me” may at least elicit “But not everyone has met you!” (2) Other times, such as before a game or a test, self-disparaging comments *prepare us for possible failure.* The coach who extols the superior strength of the upcoming opponent makes a loss understandable, a victory noteworthy. (3) A self-disparaging “How could I have been so stupid!” also helps us *learn from our mistakes.* (4) Self-disparagement frequently *pertains to one’s old self.* Asked to remember their really bad behaviors, people recall things from long ago; good behaviors more easily come to mind from their recent past (Escobedo & Adolphs, 2010). Even when they have not changed, people are much more critical of their distant past selves than of their current selves (Wilson & Ross, 2001). “At 14, I was a jerk; today I’m more sensitive.” In their own eyes, chumps yesterday, champs today.

> “*If you compare yourself with others, you may become vain and bitter; for always there will be greater and lesser persons than yourself.*”
>
> *Max Ehrmann, “Desiderata,” 1927*

Even so, all of us some of the time (and some of us much of the time) do feel inferior. This is especially true when we compare ourselves with those who are a step or two higher on the ladder of status, looks, income, or ability. Olympians who win silver medals, barely missing gold, show greater sadness on the awards podium compared with the bronze medal winners (Medvec et al., 1995). The deeper and more frequently we have such feelings, the more unhappy or even depressed we become. But for most people, thinking has a naturally positive bias.

While recognizing the dark side of excessive self-esteem, some researchers identify two types of self-esteem—defensive and secure (Kernis, 2003; Lambird & Mann, 2006; Ryan & Deci, 2004). *Defensive self-esteem* is fragile. It focuses on sustaining itself, which makes failure and criticism feel threatening. Defensive people may respond to such perceived threats with anger or aggression (Crocker & Park, 2004; Donnellan et al., 2005).

Secure self-esteem is less fragile, because it is less contingent on external evaluations. To feel accepted for who we are, and not for our looks, wealth, or acclaim, relieves pressures to succeed and enables us to focus beyond ourselves. By losing ourselves in relationships and purposes larger than ourselves, we may achieve a more secure self-esteem, satisfying relationships, and greater quality of life (Crocker & Park, 2004). Authentic pride, rooted in actual achievement, supports self-confidence and leadership (Tracy et al., 2009; Weidman et al., 2016; Williams & DeSteno, 2009).

> “*True humility is not thinking less of yourself; it is thinking of yourself less.*”

C. S. Lewis, Mere Christianity, *1952*

✓ Check Your Understanding

Ask Yourself

- What possible selves do you dream of—or fear—becoming? To what extent do these imagined selves motivate you now?

Test Yourself

- What are the positive and negative effects of high self-esteem?
- The tendency to accept responsibility for success and blame circumstances or bad luck for failure is called _______________- _______________ _______________ .
- _______________ (Secure/Defensive) self-esteem is linked to angry and aggressive behavior. _______________ (Secure/Defensive) self-esteem is a healthier self-image that allows us to focus beyond ourselves and enjoy a higher quality of life.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Culture and the Self

Flip It Video: Individualist and Collectivist Cultures

59-3 How do individualist and collectivist cultures differ in their values and goals?

Imagine that someone ripped away your social connections, making you a solitary refugee in a foreign land. How much of your identity would remain intact?

If you are an **individualist**, a great deal. You would have an independent sense of “me,” and an awareness of your unique personal convictions and values. Individualists prioritize personal goals. They define their identity mostly in terms of personal traits. They strive for personal control and individual achievement.

individualism

giving priority to one’s own goals over group goals and defining one’s identity in terms of personal attributes rather than group identifications.

Individualists do share the human need to belong. They join groups. But they are less focused on group harmony and doing their duty to the group (Brewer & Chen, 2007). Being more self-contained, individualists move in and out of social groups more easily. They feel relatively free to switch places of worship, change jobs, or even leave their extended families and migrate to a new place. Marriage is often for as long as they both shall love.

The New Yorker Collection, 2000, Jack Ziegler from cartoonbank.com.
All Rights Reserved.

If set adrift in a foreign land as a **collectivist**, you might experience a greater loss of identity. Cut off from family, groups, and loyal friends, you would lose the connections that have defined who you are. *Group identifications* provide a sense of belonging, a set of values, and an assurance of security. Collectivists have deep attachments to their groups—their family, clan, or company. Elders receive respect. For example, the *Law of the People's Republic of China on Protection of the Rights and Interests of the Elderly* states that parents aged 60 or above can sue their sons and daughters if they fail to provide "for the elderly, taking care of them and comforting them, and cater[ing] to their special needs."

collectivism

giving priority to the goals of one's group (often one's extended family or work group) and defining one's identity accordingly.

Kyodo/Reuters/Newscom

Considerate collectivists Japan’s collectivist values, including duty to others and social harmony, were on display after the devastating 2011 earthquake and tsunami. Virtually no looting was reported, and residents remained calm and orderly, as shown here while waiting for drinking water.

Collectivists are like athletes who take more pleasure in their team’s victory than in their own performance. They find satisfaction in advancing their groups’ interests, even at the expense of personal needs. They preserve group spirit by avoiding direct confrontation, blunt honesty, and uncomfortable topics. They value humility, not self-importance (Bond et al., 2012). Instead of dominating conversations, collectivists hold back and display shyness when meeting strangers (Cheek & Melchior, 1990). Given the priority on “we,” not “me,” that individualized North American latte—“skinny, extra hot, no-foam”—might sound selfishly demanding in Seoul (Kim & Markus, 1999).

A question: What do you think of people who willingly change their behavior to suit different people and situations? People in individualist countries (the United States and Brazil) typically describe them as “dishonest,” “untrustworthy,” and “insincere” (Levine, 2016). In traditionally collectivist countries (China, India, and Nepal), people more often describe them as “mature,” “honest,” “trustworthy,” and “sincere.”

> “*One needs to cultivate the spirit of sacrificing the little me to achieve the benefits of the big me.*”

Chinese saying

To be sure, there is also diversity *within* cultures. Within many countries, there are also distinct subcultures related to one's religion, economic status, and region (Cohen, 2009). In China, greater collectivist thinking occurs in provinces that have produced rice, a difficult-to-grow crop that involves cooperation to sustain irrigation (Talhelm et al., 2014). In collectivist Japan, a spirit of individualism marks the "northern frontier" island of Hokkaido (Kitayama et al., 2006). And even in the most individualist countries, people have some collectivist values. But in general, people (especially men) in competitive, individualist cultures have more personal freedom, are less geographically bound to their families, enjoy more privacy, and take more pride in personal achievements (**Table 59.1**).

TABLE 59.1 Value Contrasts Between Individualism and Collectivism

Concept	**Individualism**	**Collectivism**
Self	Independent (identity from individual traits)	Interdependent (identity from belonging to groups)
Life task	Discover and express one's uniqueness	Maintain connections, fit in, perform role
What matters	Me—personal achievement and fulfillment; rights and liberties; self-esteem	Us—group goals and solidarity; social responsibilities and relationships; family duty
Coping method	Change reality	Accommodate to reality
Morality	Defined by the individual (self-based)	Defined by social networks (duty-based)
Relationships	Many, often temporary or casual; confrontation acceptable	Few, close and enduring; harmony is valued
Attributing behavior	Behavior reflects the individual's personality and	Behavior reflects social norms and roles

	attitudes	

Information from Thomas Schoeneman (1994) and Harry Triandis (1994).

"I'D LIKE A DECAFFACINNO FRAPPA CHAPPA DAPPA DINGO ICE BLENDED LAST OF THE MOCCA-HICANS VANILLA ICE ICE BETTER LATTE´ THAN NEVER SMOOTHIE WITH A SHOT OF SELF-EXPRESSO."
hickerson

The tolerance of a Starbucks barista is severely tested.

Cartoon by Buddy Hickerson

Individualists even prefer unusual names, as psychologist Jean Twenge noticed while seeking a name for her first child. When she and her colleagues (2010, 2016) analyzed the first names of 358 million American babies born between 1880 and 2015, they discovered that the most common baby names had become less common. As **Figure 59.1** illustrates, the percentage of boys and girls given one of the 10 most common names for their birth year has plunged. Collectivist Japan provides a contrast: Half of Japanese baby names are among the country's 10 most common names (Ogihara et al., 2015).

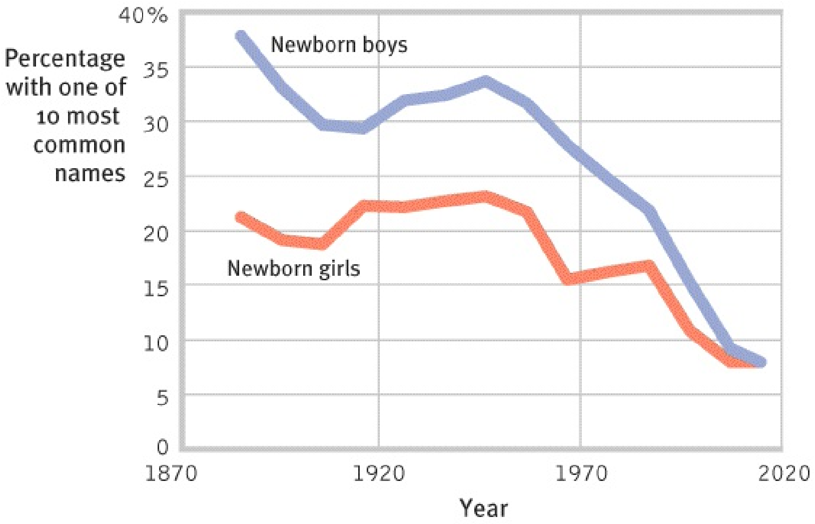

Figure 59.1
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from Twenge et al., 2010, 2016.

Figure 59.1 A child like no other

Americans' individualist tendencies are reflected in their choice of names for their babies. In recent years, the percentage of American babies receiving one of that year's 10 most common names has plunged.

The individualist-collectivist divide appeared in reactions to medals received during the 2000 and 2002 Olympic games. U.S. gold medal winners and the U.S. media covering them attributed the achievements mostly to the athletes themselves (Markus et al., 2006). "I think I just stayed focused," explained swimming gold medalist Misty Hyman. "It was time to show the world what I could do." Japan's gold medalist in the women's marathon, Naoko Takahashi, had a different explanation: "Here is the best coach in the world, the best manager in the world, and all of the people who support me—all of these things . . . became a gold medal."

Wells Fargo
Corporation

Sam Harrel/Fairbanks/AK/U.S./ZUMA Press/Newscom

Collectivist culture Although the United States is largely individualist, many cultural subgroups remain collectivist. This is true for many Alaska Natives, who demonstrate respect for tribal elders, and whose identity springs largely from their group affiliations.

Individualists demand romance and personal fulfillment in marriage (Dion & Dion, 1993). In one survey, "keeping romance alive" was rated as important to a good marriage by 78 percent of U.S. women but only 29 percent of Japanese women (*American Enterprise*, 1992). In China, love songs have often expressed enduring commitment and friendship (Rothbaum & Tsang, 1998): "We will be together from now on. . . . I will never change from now to forever."

> "*I used to subscribe to People. Then I switched to Us. Now I just read Self.*"
>
> *Lenny, quoted by Robert Levine,* Stranger in the Mirror: The Scientific Search for Self, *2016*

As cultures evolve, some trends weaken and others grow stronger. Individualism and independence have been fostered by voluntary emigration, a capitalist economy, and a sparsely populated, challenging environment (Kitayama et al., 2009, 2010; Varnum et al., 2010). In Western cultures, individualism has increased strikingly over the last century, following closely on the heels of increasing affluence (Grossmann & Varnum, 2015). This trend reached a new high in 2013 and 2014, when U.S. high school and college students reported increased acceptance of diversity, but also the greatest-ever interest in obtaining benefits for themselves and the lowest-ever willingness to donate to charity (Twenge, 2016; Twenge et al., 2012).

✓ Check Your Understanding

Ask Yourself

- Which concept best describes you—collectivist or individualist? Do you fit completely in either category, or are you sometimes a collectivist and sometimes an individualist?

Test Yourself

- How do people in individualist and collectivist cultures differ?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 59 REVIEW

59-1 Why has psychology generated so much research on the self? How important is self-esteem to our well-being?

- The *self* is the center of personality, organizing our thoughts, feelings, and actions.
- Considering possible selves helps motivate us toward positive development, but focusing too intensely on ourselves can lead to the *spotlight effect.*
- High *self-esteem* is beneficial, but unrealistically high self-esteem is dangerous (linked to aggressive behavior) and fragile. *Self-efficacy* is our sense of competence.
- Rather than unrealistically promoting children's feelings of self-worth, it is better to reward their achievements, which leads to feelings of competence.

59-2 How do excessive optimism, blindness to one's own incompetence, and self-serving bias reveal the costs of self-esteem, and how do defensive and secure self-esteem differ?

- Excessive optimism can lead to complacency and prevent us from seeing real risks, while blindness to one's own incompetence may lead us to make the same mistakes repeatedly.
- *Self-serving bias* is our normal tendency to perceive ourselves favorably, as when viewing ourselves as better than average or when accepting credit for our successes but not blame for our failures.
- *Narcissism* is excessive self-love and self-absorption.
- Defensive self-esteem is fragile, focuses on sustaining itself, and views failure or criticism as a threat. Secure self-esteem is sturdy, enabling us to feel accepted for who we are.

59-3 How do individualist and collectivist cultures differ in their values and goals?

- Although individuals vary, different cultures tend to emphasize either individualism or collectivism.
- Cultures based on self-reliant *individualism* tend to value personal independence and individual achievement. They define identity in terms of self-esteem, personal goals and attributes, and personal rights and liberties.
- Cultures based on socially connected *collectivism* tend to value group goals, social identity, and commitments. They define identity in terms of interdependence, tradition, and harmony.

Multiple-Choice Questions

1. Which of the following is an example of self-efficacy?

a. Manuela believes others are always watching her.
b. Abraham believes he is a good person.
c. Rasheed has placed in skating competitions, which makes him believe that he is a competent skater.
d. Saundra believes it rained because she’s been wishing for rain for days.
e. Igor maintains his optimism despite doing poorly in his math class.

2. Which of the following is most likely to be true of a person from an individualist culture?

a. His behavior would be a reflection of his personality and attitudes.
b. He would choose a career based on the needs of his community.
c. He would view his life task as fitting in and maintaining connections.
d. He would strive to develop a few close and enduring relationships.
e. He would focus on his duty to his family.

3. Karl was late to his interview because he left the house late and did not use his GPS for directions. If Karl is making use of the self-serving bias, which of the following statements will he use to explain his lateness?

a. “I thought I knew where I was going, but I got lost.”
b. “I spent too much time trying to find a tie that matched this shirt.”
c. “My GPS told me to turn left when I should have turned right.”
d. “I am usually right in predicting how long it takes me to get places, but today there was more traffic than I anticipated.”
e. “Sometimes I procrastinate and do not leave enough time to get places.”

Practice FRQs

1. Walking out of his AP® psychology exam, Dwight told his friends, “I did so well, they might just have to give me a 6!” Explain how each of the following might be involved in Dwight’s statement.

- Self-efficacy
- Self-esteem
- Self-serving bias

Answer

1 point: Self-efficacy would be involved if Dwight had proven readiness for the AP® exam—for example if he had done well on his teacher’s tests during the year. Page 612

1 point: Self-esteem would be involved if Dwight, in general, feels good about himself. Page 612

1 point: The self-serving bias may cause Dwight to assume he will do better than most even if he wasn’t well prepared. Page 614

2. Troy has decided to move from the United States to Japan. Describe two cultural elements that will be different for Troy when he moves.

AP® EXAM PRACTICE QUESTIONS

Multiple-Choice Questions

1. A question on the Minnesota Multiphasic Personality Inventory

(MMPI) such as “I get angry sometimes” is included to determine what about the test-taker?

- a. Whether the person has a personality disorder
- b. If the person needs immediate help for anger management
- c. If the person is more extraverted than introverted
- d. Whether the person has a stronger id or superego
- e. If the person is answering the questions truthfully

2. Albert Bandura proposed the social-cognitive perspective, which

- a. emphasizes the interaction of our traits with our situations.
- b. predicts human behavior.
- c. focuses on how our environment controls us.
- d. describes our personality using five main traits.
- e. explains the role of the inferiority complex in our behaviors.

3. According to Sigmund Freud, which of the following defense mechanisms buries threatening or upsetting events in the unconscious?

- a. Regression
- b. Displacement
- c. Repression
- d. Reaction formation
- e. Projection

4. Athletes who often privately credit their victories to their own abilities, and their losses to bad breaks, lousy officiating, or the other team’s exceptional performance, are exhibiting which psychological concept?

- a. A low self-esteem
- b. The self-serving bias
- c. Pessimism
- d. The spotlight effect
- e. Incompetence

5. Which term is defined as all the thoughts and feelings we have in response to the question, “Who am I?”

a. Self-concept
b. Ideal self
c. Self-esteem
d. Real self
e. Self-efficacy

6. Which psychologist is incorrectly matched with the theory?

a. Freud—Psychoanalytic
b. Rogers—Humanistic
c. Maslow—Trait
d. Bandura—Social-cognitive
e. Cattell—Trait

7. Which term describes questionnaires that cover a wide range of feelings and behaviors and are designed to assess several traits?

a. Factor analysis studies
b. Peer reports
c. Achievement tests
d. Cognition tests
e. Personality inventories

8. Someone from a collectivist culture is more likely to do what?

a. Develop a strong sense of self
b. Give priority to group goals
c. Form casual, often temporary relationships
d. Achieve personal goals
e. Focus on how they are different from the group

9. Critics of humanistic psychology have suggested that this theory fails to appreciate the reality of our human capacity for which of the following?

a. Empathy
b. Love
c. Evil

d. Empathy
e. Self-acceptance

0. Factor analysis is the test-development strategy that

a. develops ambiguous pictures.
b. looks to find items on a test that differentiate between groups and chooses those items for the test.
c. analyzes a person’s reciprocal determinism in a given situation.
d. analyzes the most common defense mechanisms.
e. determines how people feel about themselves in the present moment.

1. In Brad Bushman and Roy Baumeister’s research, how did people with unrealistically high self-esteem react when they were criticized?

a. They became exceptionally aggressive.
b. Many were more receptive to the criticism.
c. Some became easily depressed.
d. Most worked harder to do better the next time.
e. They quit the task without completing it.

2. Carl Rogers felt that we are our best selves when we feel accepted for who we are. What did he call this accepting attitude?

a. A peak experience
b. Unconditional positive regard
c. Self-transcendence
d. Humanistic psychology
e. Our self-concept

3. Children’s TV-viewing habits (past behavior) influence their viewing preferences (internal personal factor), which influence how television (environmental factor) affects their current behavior. What is this an example of?

a. Spotlight effect
b. Learned helplessness
c. Reciprocal determinism

d. The Big Five traits
e. Implicit learning

4. Which of the following theories offers a special focus on the potential for healthy personal growth?

a. Neo-Freudian
b. Psychodynamic
c. Humanistic
d. Behavioral
e. Functionalist

5. Elaine's friends know that she should never be trusted with a secret, as she will tell everyone almost immediately. Elaine, however, complains that her friends can't be trusted. Elaine is making use of the defense mechanism of

a. rationalization.
b. regression.
c. displacement.
d. sublimation.
e. projection.

6. Thom is 6. How would Sigmund Freud explain his resolving of his Oedipus complex?

a. He will develop a strong interest in what his father is interested in.
b. He will continue to resent his father, but also come to resent his mother.
c. He will displace his anger onto his older sister.
d. He will develop a strong superego.
e. He will develop a weak id.

7. A psychoanalytic psychologist might use the TAT and the Rorschach test in order to

a. get a glimpse of a person's ideal self.
b. determine if a person is an introvert.

c. determine if a person is conscientious.
d. gain insight about a person’s unconscious mind.
e. gain insight about where a person falls in Maslow’s hierarchy of needs.

8. The most widely used scientifically validated personality test is the

a. TAT.
b. Rorschach.
c. MMPI-2.
d. Myers-Briggs.
e. UPR self-inventory.

9. Paola and Juliana went to a baseball game and were shown on the centerfield screen. Juliana was embarrassed, because she had mustard on her face from her hot dog. In reality, no one in the crowd noticed the mustard. Juliana was overestimating how much attention people were paying to her due to the

a. self-efficacy effect.
b. self-serving bias.
c. self-transcendent effect.
d. terror-management theory.
e. spotlight effect.

Free-Response Questions

1. Briefly explain how each of the following theorists would view personality measurement, using appropriate psychological terminology.

- Psychodynamic theorists
- Humanistic theorists
- Trait theorists

Rubric for Free-Response Question 1

1 point: Psychodynamic theorists view the goal of personality measurement as revealing the unconscious conflicts and impulses that drive and create our personality. Projective tests (such as the TAT or Rorschach test) supposedly allow individuals to “project” their unconscious desires and impulses onto the test so that they are revealed to the therapist and client. Page 584

1 point: Humanistic theorists are skeptical about attempts to measure personality. They view personality tests and other attempts at measuring and quantifying personality as potentially depersonalizing, reducing the complexity of a person to one of a few generalized categories. Page 593

1 point: Trait theorists attempt to measure personality through personality inventories, such as the MMPI. They are most interested in knowing where a person fits on each of the Big Five personality factors. Pages 598–601

2. Alejandro has joined an online dating service in an attempt to meet some new people. He met a woman named Sakura through the website and agreed to go on a date with her because they have many things in common.
Explain how the following concepts could relate to Alejandro and Sakura’s date:

- Self-concept
- Self-efficacy
- Extraversion/introversion
- Spotlight effect

(4 points)

3. Maylin has a negative attitude and is disrespectful of her peers. She is unhappy at work and has not been performing at her job as well as in the past. Unfortunately, Maylin blames her co-workers for mistakes that have been made and feels as if the world is against her.

A. Explain how each of the following psychological concepts might explain Maylin’s *negative* or *unpleasant* behavior.

- Self-serving bias
- Displacement

B. Explain how each of the following psychological concepts might *help* Maylin become more positive in her daily life.

- Self-actualization
- Sublimation
- Unconditional positive regard

UNIT XI Testing and Individual Differences

Hill Street Studios/Getty Images

MODULES

60 Introduction to Intelligence

61 Assessing Intelligence

62 The Dynamics of Intelligence

63 Studying Genetic and Environmental Influences on Intelligence

64 Group differences and the question of bias

Three huge controversies have sparked debate in and beyond psychology. First is the “memory war,” over whether traumatic experiences are repressed and can later be recovered, with therapeutic benefit. Second is the “gender war,” over the extent to which nature and nurture shape our behaviors as men and women. In this unit, we meet the third great controversy, the “intelligence war”: Does each of us have an inborn general mental capacity (intelligence)? Can we quantify this capacity as a meaningful number? And can we measure intelligence without bias?

School boards, courts, and scientists debate the use and fairness of tests that assess people’s mental abilities and assign them a score. Is intelligence testing a constructive way to guide people toward suitable opportunities? Or is it a potent, discriminatory weapon camouflaged as science? First, some basic questions:

- What is intelligence?
- How can we best assess intelligence?
- How does intelligence change over time and vary among individuals?
- How do heredity and experience together weave the intelligence fabric?
- What intelligence test score similarities and differences exist among groups, and what accounts for those differences? Should we use such differences to track the abilities of students? To admit them to colleges or universities? To hire them?

This unit offers answers, by identifying a variety of mental gifts and concluding that the recipe for high achievement blends talent and grit.

Unit XI Overview Video

Module **60 Introduction to Intelligence**

LEARNING TARGETS

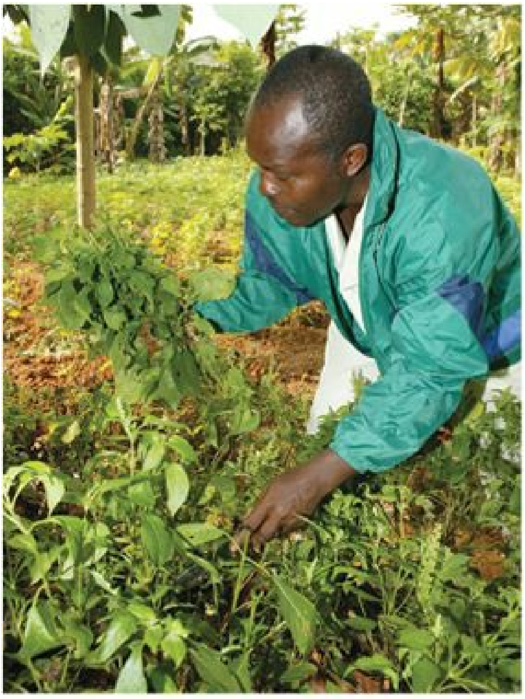
- 60-1 Discuss how psychologists define *intelligence*, and present the arguments for *g*.
- 60-2 Compare Gardner’s and Sternberg’s theories of multiple intelligences, and discuss the criticisms they have faced.
- 60-3 Describe the four components of emotional intelligence.

60-1 How do psychologists define *intelligence*, and what are the arguments for *g*?

In many studies, *intelligence* has been defined as whatever *intelligence tests* measure, which has tended to be school smarts. But intelligence is not a quality like height or weight, which have the same meaning to everyone worldwide. People assign this term to the qualities that enable success in their own time and culture (Sternberg & Kaufman, 1998). In Cameroon’s equatorial forest, *intelligence* may reflect understanding the medicinal qualities of local plants. In a North American high school, it may reflect mastering difficult concepts in calculus or chemistry. In both places, **intelligence** is the ability to learn from experience, solve problems, and use knowledge to adapt to new situations.

intelligence

the ability to learn from experience, solve problems, and use knowledge to adapt to new situations.



imageBROKER/Alamy

Hands-on healing The socially constructed concept of intelligence varies from culture to culture. This natural healer in Cameroon displays intelligence in his knowledge about medicinal plants and his understanding of the needs of the people he is helping.

You probably know some people with talents in science, others who excel in the humanities, and still others gifted in athletics, art, music, or dance. You may also know a talented artist who is stumped by the simplest math problem, or a brilliant math student who struggles when discussing literature. Are all these people intelligent? Could you rate their intelligence on a single scale? Or would you need several different scales?

AP® EXAM TIP

Your authors identified three “huge controversies” in the unit opener. All three are covered extensively in this book; be sure you can explain each of them.

Is Intelligence One General Ability?

Charles Spearman (1863–1945) believed we have one **general intelligence** (often shortened to *g*) that is at the heart of all our intelligent behavior, from navigating the sea to excelling in school. He granted that people often have special, outstanding abilities. But he noted that those who score high in one area, such as verbal intelligence, typically score higher than average in other areas, such as spatial or reasoning ability. Spearman's belief stemmed in part from his work with **factor analysis**, a statistical procedure that identifies clusters of related items.

general intelligence (*g*)

according to Spearman and others, underlies all mental abilities and is therefore measured by every task on an intelligence test.

factor analysis

a statistical procedure that identifies clusters of related items (called factors) on a test; used to identify different dimensions of performance that underlie a person's total score.

This idea of a general mental capacity expressed by a single intelligence score was controversial in Spearman's day, and so it remains. One of Spearman's early opponents was L. L. Thurstone (1887–1955). Thurstone gave 56 different tests to people and mathematically identified seven clusters of *primary mental abilities* (word fluency, verbal comprehension, spatial ability, perceptual speed, numerical ability, inductive reasoning, and memory). Thurstone did not rank people on a single scale of general aptitude. But when other investigators studied these profiles, they detected a persistent tendency: Those who excelled in one of the seven clusters generally scored well on the others. So, the investigators concluded, there was still some evidence of a *g* factor.

> “*g is one of the most reliable and valid measures in the behavioral domain . . . and it predicts important social outcomes such as educational and occupational levels far better than any other trait.*”
>
> *Behavior geneticist Robert Plomin (1999)*

We might, then, liken mental abilities to physical abilities: Athleticism is not one thing, but many. The ability to run fast is distinct from the eye-hand coordination required to throw a ball on target. Yet there remains some tendency for good things to come packaged together—for running speed and throwing accuracy to correlate. So, too, with intelligence. Several distinct abilities tend to cluster together and to correlate enough to define a general intelligence factor. Distinct brain networks enable distinct abilities, with *g* explained by their coordinated activity (Cole et al., 2015; Hampshire et al., 2012). The result is a chorus of actions orchestrated through the best possible distribution of mental resources (Carroll & Bright, 2016; Lee et al., 2015).

Theories of Multiple Intelligences

60-2 How do Gardner’s and Sternberg’s theories of multiple intelligences differ, and what criticisms have they faced?

Other psychologists, particularly since the mid-1980s, have sought to extend the definition of *intelligence* beyond the idea of academic smarts.

Gardner’s Multiple Intelligences

Howard Gardner has identified eight *relatively independent intelligences*, including the verbal and mathematical aptitudes assessed by standardized tests (**Figure 60.1**). Thus, the computer programmer, the poet, the street-smart adolescent, and the basketball team’s play-making point guard exhibit different kinds of intelligence (Gardner, 1998). Gardner (1999a) has also proposed a ninth possible intelligence—*existential intelligence*—the ability “to ponder large questions about life, death, existence.”

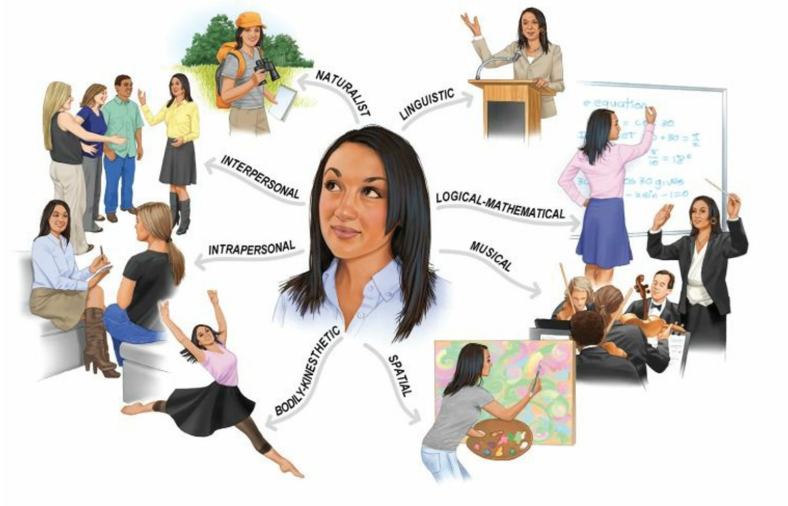


Figure 60.1
Myers/DeWall, *Myers’ Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 60.1 Gardner’s eight intelligences

Gardner has also proposed existential intelligence (the ability to ponder deep questions about life) as a ninth possible intelligence.

Gardner (1983, 2006; 2011; Davis et al., 2011) views these intelligence domains as multiple abilities that come in different packages. Brain damage, for example, may destroy one ability but leave others intact. And consider people with **savant syndrome**, who have an island of brilliance but often score low on intelligence tests and may have limited or no language ability (Treffert, 2010). Some can compute complicated calculations almost instantly, or identify the day of the week of any given historical date, or render incredible works of art or music (Miller, 1999).

savant syndrome
a condition in which a person otherwise limited in mental ability has an exceptional specific skill, such as in computation or drawing.

Then Chih Wey/Xinhua News Agency/Newscom

Islands of genius: Savant syndrome After a brief helicopter ride over Singapore followed by five days of drawing, British savant artist Stephen Wiltshire accurately reproduced an aerial view of the city from memory.

About 4 in 5 people with savant syndrome are male, and many also have *autism spectrum disorder* (*ASD;* see Module 47). The late memory whiz Kim Peek (who did not have ASD) inspired the movie *Rain Man.* It took him 8 to 10 seconds to read and remember a page. During his lifetime, he memorized 9000 books, including Shakespeare’s works and the Bible. He could provide GPS-like travel directions within any major U.S. city. Yet he could not button his clothes, and he had little capacity for abstract concepts. Asked by his father at a restaurant to lower his voice, he slid down in his chair to lower his voice box. Asked for Lincoln’s Gettysburg Address, he responded, “227 North West Front Street. But he only stayed there one night—he gave the speech the next day” (Treffert & Christensen, 2005).

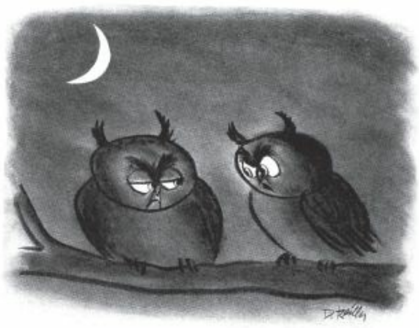
Sternberg’s Three Intelligences

Robert Sternberg (1985, 2011) agrees with Gardner that there is more to success than traditional intelligence and that we have multiple intelligences. But Sternberg’s *triarchic theory* proposes three, not eight or nine, intelligences:

- ***Analytical (academic problem-solving) intelligence*** is assessed by intelligence tests, which present well-defined problems having a single right answer. Such tests predict school grades reasonably well and vocational success more modestly.
- ***Creative intelligence*** is demonstrated in innovative smarts: the ability to adapt to new situations and generate novel ideas.
- ***Practical intelligence*** is required for everyday tasks that may be poorly defined and may have multiple solutions.

> “*You have to be careful, if you’re good at something, to make sure you don’t think you’re good at other things that you aren’t necessarily so good at. . . . Because I’ve been very successful at [software development] people come in and expect that I have wisdom about topics that I don’t.*”
>
> *Microsoft co-founder Bill Gates (1998)*

With support from the U.S. College Board (which administers the Advanced Placement Program® as well as the widely used SAT Reasoning Test to U.S. college and university applicants), Sternberg (2015) and his collaborators have developed new measures of creativity (such as thinking up a caption for an untitled cartoon) and practical thinking (such as figuring out how to move a large bed up a winding staircase). Compared to older measures, these more comprehensive assessments improve prediction of American students' first-year college grades.



Donald Reilly The New Yorker Collection/The Cartoon Bank

"You're wise, but you lack tree smarts."

Gardner and Sternberg differ in some areas, but they agree on two important points: Multiple abilities can contribute to life success, and differing varieties of giftedness bring both spice to life and challenges for education. Trained to appreciate such variety, many teachers have applied multiple intelligence theories in their classrooms.

David R. Frazier Photolibrary, Inc./Alamy

Street smarts This child selling candy on the streets of Manaus, Brazil, is developing practical intelligence at a very young age.

Criticisms of Multiple Intelligence Theories

Wouldn’t it be nice if the world were so fair that a weakness in one area would be compensated by genius in another? Alas, say critics, the world is not fair (Ferguson, 2009; Scarr, 1989). Research using factor analysis confirms that there *is* a general intelligence factor: *g* matters (Johnson et al., 2008). It predicts performance on various complex tasks and in various jobs (Gottfredson, 2002a,b, 2003a,b; see also **Figure 60.2**). And extremely high cognitive ability scores predict exceptional achievements, such as doctoral degrees and publications (Kuncel & Hezlett, 2010).

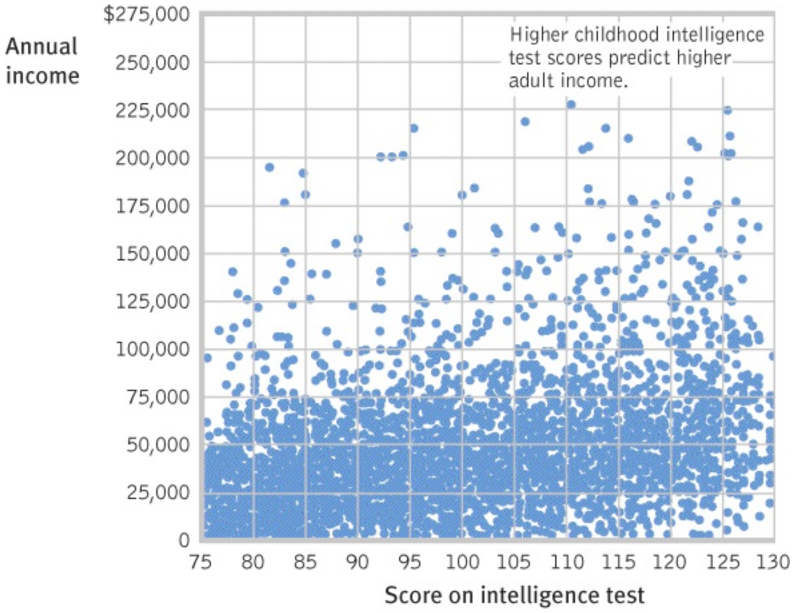


Figure 60.2
Myers/DeWall, *Myers’ Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 60.2 Smart and rich?

Jay Zagorsky (2007) tracked 7403 participants in the U.S. National Longitudinal Survey of Youth across 25 years. As shown in this illustrative scatterplot, their intelligence scores correlated +.30, a moderate positive correlation, with their later income.

Courtesy of Cameras on Wheels

Spatial intelligence genius In 1998, World Checkers Champion Ron “Suki” King of Barbados set a new record by simultaneously playing 385 players in 3 hours and 44 minutes. Thus, while his opponents often had hours to plot their game moves, King could only devote about 35 seconds to each game. Yet he still managed to win all 385 games!

Even so, “success” is not a one-ingredient recipe. High intelligence may help you get into a good college and ultimately a desired profession, but it won’t make you successful once there. Success is a combination of talent and **grit:** Those who become highly successful tend also to be conscientious, well-connected, and doggedly energetic. K. Anders Ericsson and others report a *10-year rule:* A common ingredient of expert performance in chess, dance, sports, computer programming, music, and medicine is “about 10 years of intense, daily practice” (Ericsson, 2007; Ericsson & Pool, 2016; Simon & Chase, 1973). Becoming a professional musician or an elite athlete requires, first, native ability (Macnamara et al., 2014, 2016). But it also requires years of practice—about 11,000 hours on average, and a *minimum* of 3000 hours (Campitelli & Gobet, 2011). The recipe for success is a gift of nature plus a whole lot of nurture.

grit

in psychology, grit is passion and perseverance in the pursuit of long-term goals.

Emotional Intelligence

60-3 What are the four components of emotional intelligence?

Some psychologists have further explored our *social intelligence*—the know-how involved in understanding social situations and managing ourselves successfully (Cantor & Kihlstrom, 1987). Psychologist Edward Thorndike first proposed the concept in 1920, noting that "the best mechanic in a factory may fail as a foreman for lack of social intelligence" (Goleman, 2006, p. 83).

A critical part of social intelligence, **emotional intelligence**, consists of four abilities (Mayer et al., 2002, 2016):

- *Perceiving* emotions (recognizing them in faces, music, and stories, and identifying one's own emotions)
- *Understanding* emotions (predicting them and how they may change and blend)
- *Managing* emotions (knowing how to express them in varied situations, and how to manage others' emotions)
- *Using* emotions to facilitate adaptive or creative thinking

emotional intelligence

the ability to perceive, understand, manage, and use emotions.

TRY THIS

For more on how self-disciplined grit feeds achievement, see Module 40.

Emotionally intelligent people are both socially aware and self-aware. They avoid being hijacked by overwhelming depression, anxiety, or anger. They can read others' emotional cues and know what to say to soothe a grieving friend, encourage a workmate, and manage a conflict. They can delay gratification in pursuit of long-range rewards. Thus, emotionally intelligent people more often succeed in relationship, career, and parenting situations than do academically smarter but less emotionally intelligent people (Cherniss, 2010a,b; Czarna et al., 2016; Miao et al., 2016). They also tend to be happy and healthy (Sánchez-Álvarez et al., 2016; Schutte et al., 2007, 2016). Aware of these benefits, school-based programs have sought to increase teachers' and students' emotional intelligence (Nathanson et al., 2016).

FYI

The procrastinator's motto: "Hard work pays off later; laziness pays off now."

AP® EXAM TIP

Familiarize yourself with Table 60.1. Be able to compare and contrast the contributions of the intelligence theorists (e.g., Spearman, Gardner, Sternberg).

Some scholars, however, are concerned that emotional intelligence stretches the intelligence concept too far (Visser et al., 2006). Howard Gardner (1999b) includes interpersonal and intrapersonal intelligences as two of his multiple intelligences. But he notes that we should respect emotional sensitivity, creativity, and motivation as important but different. Stretch *intelligence* to include everything we prize and the word will lose its meaning.

* * *

For a summary of these theories of intelligence, see **Table 60.1**.

TABLE 60.1 Comparing Theories of Intelligence

Theory	**Summary**	**Strengths**	**Other Considerations**

Spearman's general intelligence (g)	A basic intelligence predicts our abilities in varied academic areas.	Different abilities, such as verbal and spatial, do have some tendency to correlate.	Human abilities are too diverse to be encapsulated by a single general intelligence factor.
Thurstone's primary mental abilities	Our intelligence may be broken down into seven distinct factors.	A single *g* score is not as informative as scores for seven primary mental abilities.	Even Thurstone's seven mental abilities show a tendency to cluster, suggesting an underlying *g* factor.
Gardner's multiple intelligences	Our abilities are best classified into eight or nine independent intelligences, which include a broad range of skills beyond traditional school smarts.	Intelligence is more than just verbal and mathematical skills. Other abilities are equally important to our human adaptability.	Should all our abilities be considered *intelligences?* Shouldn't some be called less vital *talents?*
Sternberg's triarchic theory	Our intelligence is best classified into three areas that predict real-world success: analytical, creative, and practical.	These three domains can be reliably measured.	These three domains may be less independent than Sternberg thought and may actually share an underlying *g* factor.
Emotional intelligence	Social intelligence is an important indicator of life success. Emotional intelligence is a key aspect, consisting of perceiving, understanding, managing, and using	These four components predict social success and emotional well-being.	Does this stretch the concept of intelligence too far?

	emotions.		

Check Your Understanding

Ask Yourself

- The modern concept of multiple intelligences (as proposed by Gardner and Sternberg) assumes that the analytical school smarts measured by traditional intelligence tests are important abilities but that other abilities are also important. Different people have different gifts. What are yours?

Test Yourself

- How does the existence of savant syndrome support Gardner’s theory of multiple intelligences?
- Joseph, a Harvard Law School student, has a straight-A average, writes for the *Harvard Law Review*, and will clerk for a Supreme Court justice next year. His grandmother, Judith, is very proud of him, saying he is far more intelligent than she ever was. But Joseph is also very proud of Judith: As a young woman, she was imprisoned by the Nazis. When the war ended, she walked out of Germany, contacted an agency helping refugees, and began a new life in the United States as an assistant chef in her cousin’s restaurant. According to the definition of intelligence in this unit, is Joseph the only intelligent person in this story? Why or why not?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 60 REVIEW

60-1 How do psychologists define *intelligence*, and what are the arguments for *g*?

- *Intelligence* is a mental quality consisting of the ability to learn from experience, solve problems, and use knowledge to adapt to new situations.
- Charles Spearman proposed that we have one *general intelligence (g)*. Through his work with *factor analysis*, a statistical procedure that identifies clusters of related mental abilities, he noted that those who score high in one area typically score higher than average in other areas.
- L. L. Thurstone disagreed and identified seven different clusters of mental abilities. Yet a tendency remained for high scorers in one cluster to score high in other clusters, providing further evidence of a *g* factor.

60-2 How do Gardner's and Sternberg's theories of multiple intelligences differ, and what criticisms have they faced?

- Howard Gardner proposed eight independent intelligences (linguistic, logical-mathematical, musical, spatial, bodily-kinesthetic, intrapersonal, interpersonal, and naturalist), as well as a possible ninth (existential intelligence). The different intelligences of people with *savant syndrome*, autism spectrum disorder (ASD), and certain kinds of brain damage seem to support his view.
- Robert Sternberg's triarchic theory proposes three intelligence areas that predict real-world skills: analytical (academic problem solving), creative, and practical.
- Critics note that while high intelligence may open doors, success in school, at work, or at a sport or hobby is a combination of talent and *grit*.

60-3 What are the four components of emotional intelligence?

- *Emotional intelligence,* which is an aspect of social intelligence, is the ability to perceive, understand, manage, and use emotions.
- Emotionally intelligent people tend to be happy, healthy, and more successful in their personal and professional lives.
- Some critics question whether calling these abilities “intelligence” stretches that concept too far.

Multiple-Choice Questions

1. An intelligence test that asks a person how many uses they can think of for a golf ball is most likely testing a person’s _____ intelligence.

a. linguistic
b. practical
c. creative
d. spatial
e. analytical

2. According to Charles Spearman and others, _____ underlies specific mental abilities and is measured by every task on an intelligence test.

a. savant syndrome
b. general intelligence (*g*)
c. factor analysis
d. intelligence
e. emotional intelligence

3. Victor is blind, unable to speak, and understands very few words. He is, however, able to hear a piece of music once and play it back flawlessly on the piano. Victor’s abilities best represent someone with

a. analytical intelligence.
b. a high *g* factor.
c. savant syndrome.
d. emotional intelligence.

   e. intrapersonal intelligence.

4. Which of the following is not a component of emotional intelligence?

   a. Understanding emotions
   b. Perceiving emotions
   c. Using emotions
   d. Managing emotions
   e. Inventing emotions

Practice FRQs

1. Give a summary, a strength, and a weakness of Charles Spearman's idea of general intelligence.

Answer

1 point: Spearman suggested we have a general intelligence—an underlying mental ability—that predicts performance for all intelligent behavior. Page 626

1 point: Strength: Different abilities, such as verbal and spatial, do tend to correlate. Page 626

1 point: Weakness: Human abilities are too diverse to be explained by a single general intelligence factor. Page 627

2. Mark and Bill are planning to open a piano-moving business and are hoping for great success. Explain how each element of Sternberg's intelligence theory could help them be successful in their business.

(3 points)

Module **61 Assessing Intelligence**

LEARNING TARGETS

- 61-1 Describe the characteristics of an *intelligence test*, and distinguish between achievement and aptitude tests.
- 61-2 Discuss when and why intelligence tests were created, and explain how today's tests differ from early intelligence tests.
- 61-3 Describe the *normal curve*, and explain *standardization*, *reliability*, and *validity*.

61-1 What is an *intelligence test*, and how do achievement and aptitude tests differ?

An **intelligence test** assesses people's mental aptitudes and compares them with those of others, using numerical scores. How do we design such tests, and what makes them credible?

intelligence test

a method for assessing an individual's mental aptitudes and comparing them with those of others, using numerical scores.

By this point in your life, you've faced dozens of ability tests: school tests of basic reading and math skills, class quizzes and tests, intelligence tests, or maybe a driver's license exam. Psychologists classify such tests as either **achievement tests**, intended to *reflect* what you have learned, or **aptitude tests**, intended to *predict* your ability to learn a new skill. Exams covering what you have learned in this course (like the AP® exam) are achievement tests. A college entrance exam, which seeks to predict your ability to do college work, is an aptitude test—a “thinly disguised intelligence test,” says Howard Gardner (1999b). Indeed, total scores on the U.S. SAT have correlated +0.82 with general intelligence test scores in a national sample of 14- to 21-year-olds (Frey & Detterman, 2004; **Figure 61.1**).

achievement test

a test designed to assess what a person has learned.

aptitude test

a test designed to predict a person’s future performance; *aptitude* is the capacity to learn.

Figure 61.1 Close cousins: Aptitude and intelligence test scores

A scatterplot shows the close correlation that has existed between intelligence test scores and SAT scores.

Early and Modern Tests of Mental Abilities

61-2 When and why were intelligence tests created, and how do today’s tests differ from early intelligence tests?

Some societies emphasize the collective welfare of the family, community, and society. Other societies focus on promoting individual opportunity. Plato, a pioneer of the individualist tradition, wrote more than 2000 years ago in *The Republic* that “no two persons are born exactly alike; but each differs from the other in natural endowments, one being suited for one occupation and the other for another.” As heirs to Plato’s individualism, people in Western societies have pondered how and why individuals differ in mental ability.

AP® EXAM TIP

Become familiar with the key contributors in intelligence testing and be able to identify how they differ (e.g., Galton, Binet, Terman).

Francis Galton: Presuming Hereditary Genius

Western attempts to assess such differences began in earnest with English scientist Francis Galton (1822–1911), who was fascinated with measuring human traits. When his cousin Charles Darwin proposed that nature selects successful traits through the survival of the fittest, Galton wondered if it might be possible to measure “natural ability” and to encourage those of high ability to mate with one another. At the 1884 London Health Exhibition, more than 10,000 visitors received his assessment of their “intellectual strengths” based on such things as reaction time, sensory acuity, muscular power, and body proportions. But alas, on these measures, well-regarded adults and students did not outscore others. Nor did the measures correlate with each other.

Although Galton’s quest for a simple intelligence measure failed, he gave us some statistical techniques that we still use (as well as the phrase *nature and nurture*). And his persistent belief in the inheritance of genius—reflected in his book, *Hereditary Genius*—illustrates an important lesson from both the history of intelligence research and the history of science: Although science itself strives for objectivity, individual scientists are affected by their own assumptions and attitudes.

Alfred Binet: Predicting School Achievement

Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Alfred Binet (1857–1911) "Some recent philosophers have given their moral approval to the deplorable verdict that an individual's intelligence is a fixed quantity, one which cannot be augmented. We must protest and act against this brutal pessimism" (Binet, 1909, p. 141).

Modern intelligence testing traces its birth to early twentieth-century France, where a new law required all children to attend school. French officials knew that some children, including many newcomers to Paris, would struggle and need special classes. But how could the schools make fair judgments about children's learning potential? Teachers might assess children who had little prior education as slow learners. Or they might sort children into classes by their social backgrounds. To minimize such bias, France's minister of public education gave psychologist Alfred Binet the task of designing fair tests.

Binet and his student, Théodore Simon, began by assuming that all children follow the same course of intellectual development but that some develop more rapidly (Nicolas & Levine, 2012). A “dull” child should score much like a typical younger child, and a “bright” child like a typical older child. Thus, their goal became measuring each child’s **mental age**, the level of performance typically associated with a certain chronological age. The average 9-year-old, then, has a mental age of 9. Children with below-average mental ages, such as 9-year-olds who perform at the level of typical 7-year-olds, would struggle with age-appropriate schoolwork.

mental age

a measure of intelligence test performance devised by Binet; the level of performance typically associated with children of a certain chronological age. Thus, a child who does as well as an average 8-year-old is said to have a mental age of 8.

To measure mental age, Binet and Simon theorized that mental aptitude, like athletic aptitude, is a general capacity that shows up in various ways. They tested a variety of reasoning and problem-solving questions on Binet’s two daughters, and then on “bright” and “backward” Parisian schoolchildren. Items answered correctly could then predict how well other French children would handle their schoolwork.

Binet and Simon made no assumptions concerning *why* a particular child was slow, average, or precocious. Binet personally leaned toward an environmental explanation. To raise the capacities of low-scoring children, he recommended “mental orthopedics” that would help develop their attention span and self-discipline. He believed his intelligence test did not measure inborn intelligence as a scale measures weight. Rather, it had a single practical purpose: to identify French schoolchildren needing special attention. Binet hoped his test would be used to improve children’s education, but he also feared it would be used to label children and limit their opportunities (Gould, 1981).

Lewis Terman: Measuring Innate Intelligence

Binet’s fears were realized soon after his death in 1911, when others adapted his tests for use as a numerical measure of inherited intelligence. Stanford University professor Lewis Terman (1877–1956) tried the Paris-developed questions and age norms with California schoolchildren. But the French norms didn’t work with California kids. Adapting some of Binet’s original items, adding others, and establishing new age norms, Terman extended the upper end of the test’s range from teenagers to “superior adults.” He also gave his revision the name today’s version retains—the **Stanford-Binet**. For Terman, intelligence tests revealed the intelligence with which a person was born.

Stanford-Binet

the widely used American revision (by Terman at Stanford University) of Binet’s original intelligence test.

From such tests, German psychologist William Stern derived the famous term **intelligence quotient**, or **IQ**. The IQ was simply a person’s mental age divided by chronological age and multiplied by 100 to get rid of the decimal point. Thus, an average child, whose mental and chronological ages are the same, has an IQ of 100. But an 8-year-old who answers questions as would a typical 10-year-old has an IQ of 125:

$$\text{IQ}=\text{mental age of 10}\text{chronological age of 8}\times 100=125$$

intelligence quotient (IQ)

defined originally as the ratio of mental age (*ma*) to chronological age (*ca*) multiplied by 100 (thus, IQ = *ma/ca* × 100). On contemporary intelligence tests, the average performance for a given age is assigned a score of 100.

The original IQ formula worked fairly well for children but not for adults. (Should a 40-year-old who does as well on the test as an average 20-year-old be assigned an IQ of only 50?) Most current intelligence tests, including the Stanford-Binet, no longer compute an IQ in this manner (though the term *IQ* still lingers as a shorthand expression for “intelligence test score”). Instead, they assign a score that represents a test-taker’s performance *relative to the average performance* (which is arbitrarily set at 100) of others the same age. Intelligence test scores for most people—about 68 percent—fall between 85 and 115.

Mrs. Randolph takes mother’s pride too far.

Terman (1916, p. 4) promoted the widespread use of intelligence testing to “take account of the inequalities of children in original endowment” by assessing their “vocational fitness.” He sympathized with Francis Galton’s *eugenics*—the much-criticized nineteenth-century movement that proposed measuring human traits and using the results to restrict reproduction among those deemed not smart and fit. Terman envisioned that the use of intelligence tests would “ultimately result in curtailing the reproduction of feeble-mindedness and in the elimination of an enormous amount of crime, pauperism, and industrial inefficiency” (p. 7).

With Terman’s help, the U.S. government developed new tests to evaluate both newly arriving immigrants and World War I army recruits—the world’s first mass administration of an intelligence test. To some psychologists, the results indicated the inferiority of people not sharing their Anglo-Saxon heritage.

> “*The IQ test was invented to predict academic performance, nothing else. If we wanted something that would predict life success, we’d have to invent another test completely.*”
>
> *Social psychologist Robert Zajonc (1984)*

Binet probably would have been horrified that his test had been adapted and used to draw such conclusions. Indeed, such sweeping judgments became an embarrassment to most of those who championed testing. Even Terman came to appreciate that test scores reflected not only people’s innate mental abilities but also their education, native language, and familiarity with the culture assumed by the test. Abuses of the early intelligence tests, such as in immigrant screening, serve to remind us that science can be value-laden. Behind a screen of scientific objectivity, ideology sometimes lurks.

✓ Check Your Understanding

Ask Yourself

- What achievement or aptitude tests have you taken? In your opinion, how well did these tests predict what you’d learned or what you were capable of learning?

Test Yourself

- What did Binet hope to achieve by establishing a child’s mental age?
- What is the IQ of a 4-year-old with a mental age of 5?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

David Wechsler: Testing Separate Strengths

Psychologist David Wechsler created what is now the most widely used individual intelligence test, the **Wechsler Adult Intelligence Scale (WAIS)**, together with a version for school-age children (the *Wechsler Intelligence Scale for Children [WISC]*) and another for preschool children

(Evers et al., 2012). The latest (2008) edition of the WAIS consists of 15 subtests, including these:

- *Similarities*—reasoning the commonality of two objects or concepts ("In what way are wool and cotton alike?")
- *Vocabulary*—naming pictured objects, or defining words ("What is a guitar?")
- *Block Design*—visual abstract processing ("Using the four blocks, make one just like this.") - *Letter-Number Sequencing*—on hearing a series of numbers and letters, repeating the numbers in ascending order, and then the letters in alphabetical order ("R-2-C-1-M-3")

Wechsler Adult Intelligence Scale (WAIS)
the WAIS and its companion versions for children are the most widely used intelligence tests; they contain verbal and performance (nonverbal) subtests.

The WAIS yields not only an overall intelligence score, as does the Stanford-Binet, but also individual scores for verbal comprehension, perceptual organization, working memory, and processing speed. Striking differences among these individual scores can provide clues to cognitive strengths or weaknesses. For example, a low verbal comprehension score combined with high scores on other subtests could indicate a reading or language disability. Other comparisons can help a psychologist or psychiatrist establish a rehabilitation plan for a stroke patient. In such ways, these tests help realize Binet's aim: to identify opportunities for improvement and strengths that teachers and others can build upon. Such uses are possible, of course, only when we can trust the test results.

Richard T. Nowitz/Getty Images

Matching patterns Block design puzzles test visual abstract processing ability. Wechsler’s individually administered intelligence test comes in forms suited for adults and children.

Principles of Test Construction

61-3 What is a *normal curve*, and what does it mean to say that a test has been *standardized* and is *reliable* and *valid*?

To be widely accepted, a psychological test must meet three criteria: It must be *standardized*, *reliable*, and *valid*. The Stanford-Binet and Wechsler tests meet these requirements.

Standardization

The number of questions you answer correctly on an intelligence test would reveal almost nothing. To know how well you performed, you would need some basis for comparison. That’s why test-makers give new tests to a representative sample of people. The scores from this pretested group become the basis for future comparisons. If you then take the test following the same procedures, your score will be meaningful when compared with others. This process is called **standardization**.

standardization

defining uniform testing procedures and meaningful scores by comparison with the performance of a pretested group.

If we construct a graph of test-takers’ scores, the scores typically form a bell-shaped pattern called the *bell curve*, or **normal curve**. No matter what attributes we measure—height, weight, or mental aptitude—the curve’s highest point is the average score. On an intelligence test, we give this average score a value of 100 (**Figure 61.2**). Moving out from the average toward either extreme, we find fewer and fewer people. For both the Stanford-Binet and Wechsler tests, a person’s score indicates whether that person’s performance fell above or below the average. A performance higher than all but 2.5 percent of all scores earns an intelligence score of 130. A performance lower than 97.5 percent of all scores earns an intelligence score of 70.

normal curve
the bell-shaped curve that describes the distribution of many physical and psychological attributes. Most scores fall near the average, and fewer and fewer scores lie near the extremes.

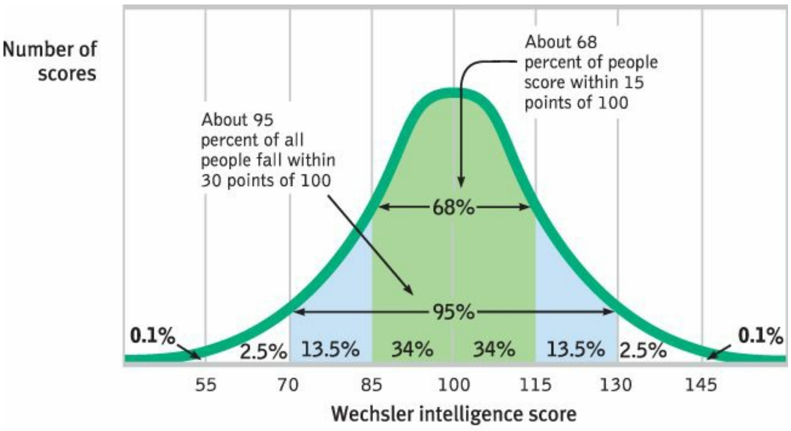

Figure 61.2
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 61.2 The normal curve

Scores on aptitude tests tend to form a normal, or bell-shaped, curve around an average score. For the Wechsler scale, for example, the average score is 100.

To keep the average score near 100, the Stanford-Binet and Wechsler scales are periodically restandardized. If you recently took the WAIS, Fourth Edition, your performance was compared with a standardization sample who took the test during 2007, not to David Wechsler's initial 1930s sample. If you compared the performance of the most recent standardization sample with that of the 1930s sample, do you suppose you would find rising or declining test performance? Amazingly—given that college entrance aptitude scores have sometimes dropped, such as during the 1960s and 1970s—intelligence test performance has improved. This worldwide phenomenon is called the *Flynn effect*, in honor of New Zealand researcher James Flynn (1987, 2012), who first calculated its magnitude. The average person’s intelligence test score in 1920 was—by today’s standard—only a 76. Such rising performance has been observed in 48 countries, from Canada to Cameroon (Wongupparaj et al., 2015). Although there have been some regional reversals, the historic increase is now widely accepted as an important phenomenon (Lynn, 2009; Teasdale & Owen, 2005, 2008).

AP® EXAM TIP

Can you remember why the intelligence test scores in Figure 61.2 are marked off in 15-point intervals? Do the 68 percent and 95 percent areas seem familiar? They should—you’ve seen this graph before. It’s Figure 8.3 from the module on statistical reasoning. Intelligence tests are being used to illustrate that 68 percent of a population will be within one standard deviation of the mean for normally distributed data. Ninety-five percent will be within two standard deviations.

The Flynn effect’s cause has been a psychological mystery. Did it result from greater test sophistication? *No.* Gains appeared before testing was widespread. Perhaps better nutrition? Thanks to improved nutrition, people have gotten taller as well as smarter. But in postwar Britain, notes Flynn (2009), the lower-class children gained the most from improved nutrition, yet the intelligence performance gains were greater among upper-class children. Might the explanation be greater educational opportunities, smaller families, and rising living standards (Pietschnig & Voracek, 2015; Rindermann et al., 2016)? Flynn (2012) attributes the performance increase to our need to develop new mental skills to cope with modern environments. Regardless of what combination of factors explains the rise in intelligence test scores, the phenomenon counters a concern of some who see intelligence as inherited—that the higher twentieth-century birthrates among those with lower scores would shove human intelligence scores downward (Lynn & Harvey, 2008).

Reliability

Knowing where you stand in comparison to a standardization group still won't say much about your intelligence unless the test has **reliability**. A reliable test gives consistent scores, no matter who takes the test or when they take it. To check a test's reliability, researchers test people many times. They may split the test in half (*split-half:* agreement of odd-question scores and even-question scores), test with alternative forms of the test, or retest with the same test (*test-retest*). The higher the *correlation* between the two scores, the higher the test's reliability. The tests we have considered—the Stanford-Binet, the WAIS, and the WISC—are very reliable after early childhood (about +0.9). When retested, people's scores generally match their first score closely.

reliability
the extent to which a test yields consistent results, as assessed by the consistency of scores on two halves of the test, on alternative forms of the test, or on retesting.

Validity

High reliability does not ensure a test's **validity**—the extent to which the test actually measures or predicts what it promises. Imagine using an inaccurate tape measure to measure people's heights. Your results would be very reliable. No matter how many times you measured, people's heights would be the same. But your faulty height results would not be valid.

validity
the extent to which a test measures or predicts what it is supposed to. (See also *content validity* and *predictive validity*.)

Tests that tap the pertinent behavior, or *criterion*, have **content validity**. The road test for a driver's license has content validity because it samples the tasks a driver routinely faces. Course exams have content validity if they assess one’s mastery of course material. But we expect intelligence tests to have **predictive validity**: They should predict the criterion of future performance, and to some extent they do.

content validity

the extent to which a test samples the behavior that is of interest.

predictive validity

the success with which a test predicts the behavior it is designed to predict; it is assessed by computing the correlation between test scores and the criterion behavior. (Also called *criterion-related validity*.)

Are general aptitude tests as predictive as they are reliable? As critics are fond of noting, the answer is *No.* Aptitude test scores do predict school grades (Roth et al., 2015). But the critics are right that the predictive power of aptitude tests peaks in the early school years and weakens later. Academic aptitude test scores are reasonably good predictors of achievement for children ages 6 to 12, where the correlation between intelligence score and school performance is about +0.6 (Jensen, 1980). Intelligence scores correlate even more closely with scores on *achievement tests:* +0.81 in one comparison of 70,000 English children’s intelligence scores at age 11 with their academic achievement in national exams at age 16 (Deary et al., 2007, 2009b). The SAT, used in the United States as a college entrance exam, has been less successful in predicting first-year college grades. (The correlation, less than +0.5, has been, however, a bit higher when adjusting for high scorers electing tougher courses [Berry & Sackett, 2009; Willingham et al., 1990].) By the time we get to the Graduate Record Examination (GRE; an aptitude test similar to the SAT but for those applying to graduate school), the correlation with graduate school performance is an even more modest but still significant +0.4 (Kuncel & Hezlett, 2007).

AP$^{®}$ EXAM TIP

Be prepared for a question about the distinction between *reliability* and *validity*, and how psychologists assess each.

FYI

Ironically, SAT exam (for college entrance) and GRE scores (for graduate school entrance) correlate better with each other than either does with its intended criterion, school achievement. Thus, their reliability far exceeds their predictive validity. If either test was much affected by coaching, luck, or how one feels on the test day (as so many people believe), such reliability would be impossible.

Why does the predictive power of aptitude scores diminish as students move up the educational ladder? Consider a parallel situation: Among all American and Canadian football linemen, body weight correlates with success. A 300-pound player tends to overwhelm a 200-pound opponent. But within the narrow 280- to 320-pound range typically found at the professional level, the correlation between weight and success becomes negligible (**Figure 61.3**). The narrower the *range* of weights, the lower the predictive power of body weight becomes. If an elite university takes only those students who have very high aptitude scores, and then gives them a restricted range of high grades, those scores cannot possibly predict much. This will be true even if the test has excellent predictive validity with a more diverse sample of students. Likewise, modern grade inflation (more students getting high grades) has produced less diverse high school grades. With their diminished range, high school grades now predict college grades no better than have SAT scores (Sackett et al., 2012). So, when we validate a measure using a wide range of scores but then use it with a restricted range of scores, it loses much of its predictive validity.

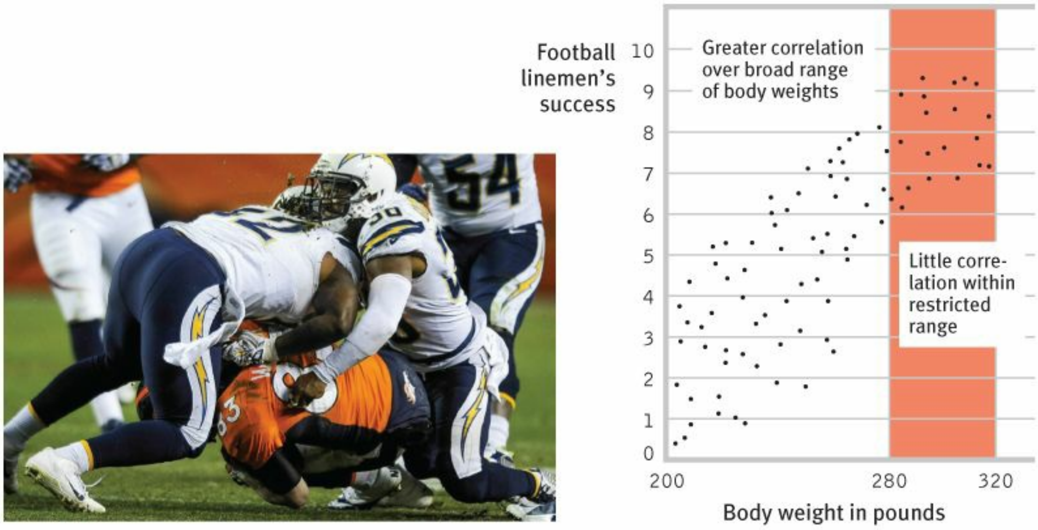

Figure 61.3
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Photo: Colorado Springs Gazette/Getty Images

Figure 61.3 Diminishing predictive power

Let's imagine a correlation between football linemen's body weight and their success on the field. Note how insignificant the relationship becomes when we narrow the range of weight to 280 to 320 pounds. As the range of data under consideration narrows, its predictive power diminishes.

✓ Check Your Understanding

Ask Yourself

- Are you working to the potential reflected in your standardized test scores? What, other than your aptitude, is affecting your school performance?

Test Yourself

- An employer with a pool of applicants for a single available position is interested in testing each applicant's potential. To determine that, she should use an ________________ (achievement/aptitude) test. That same employer wishing to test the effectiveness of a new, on-the-job training program would be wise to use an ________________ (achievement/aptitude) test.
- What are the three criteria that a psychological test must meet in order to be widely accepted? Explain.
- Correlation coefficients were used in this section. Here's a quick review:

Correlations do not indicate cause-effect, but they do tell us whether two things are associated in some way. A correlation of −1.00 represents perfect _______________ (agreement/disagreement) between two sets of scores: As one score goes up, the other score goes _______________ (up/down). A correlation of _______________ represents no association. The highest correlation, +1.00, represents perfect _______________ (agreement/disagreement): As the first score goes up, the other score goes _______________ (up/down).

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 61 REVIEW

61-1 What is an *intelligence test*, and how do achievement and aptitude tests differ?

- An *intelligence test* assesses people’s mental aptitudes and compares them with those of others, using numerical scores.
- *Achievement tests* are designed to assess what you have learned.
- *Aptitude* tests are designed to predict what you can learn.
- The *WAIS* (*Wechsler Adult Intelligence Scale),* an aptitude test, is the most widely used intelligence test for adults.

61-2 When and why were intelligence tests created, and how do today’s tests differ from early intelligence tests?

- In the late 1800s, Francis Galton, who believed that genius was inherited, attempted but failed to construct a simple intelligence test. His hope had been to identify those with exceptional abilities and encourage them to reproduce.
- In France in 1904, Alfred Binet, who tended toward an environmental explanation of intelligence differences, started the modern intelligence-testing movement by developing questions to measure children’s *mental age* and thus predict progress in the school system. Binet hoped his test would be used to improve children’s education rather than to limit their opportunities.
- During the early twentieth century, Lewis Terman of Stanford University revised Binet’s work for use in the United States.
  - Terman believed intelligence is inherited, and he thought his *Stanford-Binet* could help guide people toward appropriate opportunities.
  - During this period, intelligence tests were sometimes used to document scientists’ misguided assumptions about the innate

inferiority of certain ethnic and immigrant groups.

61-3 What is a *normal curve*, and what does it mean to say that a test has been *standardized* and is *reliable* and *valid?*

- The distribution of test scores often forms a *normal* (bell-shaped) *curve* around the central average score, with fewer and fewer scores at the extremes.
- *Standardization* establishes a basis for meaningful score comparisons by giving a test to a representative sample of future test-takers.
- *Reliability* is the extent to which a test yields consistent results (on two halves of the test, or when people are retested).
- *Validity* is the extent to which a test measures or predicts what it is supposed to.
    - A test has *content validity* if it samples the pertinent behavior (as a driving test measures driving ability).
    - It has *predictive validity* if it predicts a behavior it was designed to predict. (Aptitude tests have predictive ability if they can predict future achievements.)

Multiple-Choice Questions

1. A test developer defines uniform testing procedures and meaningful scores by comparison with the performance of a pretested group. Which of the following best describes this process?

a. Reliability testing
b. Validation
c. Content validation
d. Standardization
e. Predictive validity

2. Which of the following is the best example of an aptitude test?

a. Atul answers questions about the rules of the road.

   b. Mr. Anderson's AP® psychology test covers the material from the current unit.
   c. Sherjeel takes the ACT for college admission.
   d. Jeffrey is required to translate 50 Mandarin sentences for his final exam.
   e. Lucy and Meghan discuss what they might study in college.

3. If a test yields consistent results upon retesting, it can be said to have a high degree of

   a. reliability.
   b. validity.
   c. content validity.
   d. predictive validity.
   e. normal curve.

4. Which of the following can be used to demonstrate that only about 2 percent of the population scores at least two standard deviations above the mean on an intelligence test?

   a. Reliability test
   b. Aptitude test
   c. Predictive validity test
   d. Test-retest procedure
   e. Normal curve

Practice FRQs

1. Ms. Pilai has given her class their final exam and has discovered that their scores formed a perfect normal curve, with a standard deviation of 10.

- If the mean score of the test was 72, what percentage of students scored between 62 and 82?
- What range of scores would be within three standard deviations of the mean?
- What percentage of the scores would be within two standard

deviations of the mean?

Answer

1 point: 68 percent of the students would have scored between 62 and 82—within one standard deviation of the mean. Page 636

1 point: The range of scores within three standard deviations would be 42–102. Page 636

1 point: 95 percent of all scores would be within two standard deviations of the mean. Page 636

2. Name and briefly describe the three essential principles of test construction.

(3 points)

Module **62 The Dynamics of Intelligence**

LEARNING TARGETS

- 62-1 Analyze how aging affects crystallized and fluid intelligence.
- 62-2 Define *cross-sectional studies* and *longitudinal studies*, and explain why it is important to know which method was used.
- 62-3 Describe the stability of intelligence test scores over the life span.
- 62-4 Discuss the traits of those at the low and high intelligence extremes.

Researchers are exploring some age-old questions about human intelligence. You know it: You are smarter than some people and not as smart as others. So what in that heart of smarts—the brain—creates this difference? Is it our brain’s relative *size?* Our amounts of certain brain *tissue?* Our brain networks’ *speed?* These are among the possibilities that researchers have identified.

Here we will focus on two other questions: How stable is intelligence over the life span? (Will the precocious 5-year-old mature into a talented college student and a brilliant senior citizen?) And what are the traits and talents of those at the low and high extremes of intelligence?

Stability or Change?

What happens to our intellectual muscles as we age? Do they gradually decline, as does our body strength? Or do they remain constant? To see how psychologists have studied intelligence, see Thinking Critically About: Cross-Sectional and Longitudinal Studies. The quest for answers to these questions illustrates psychology's self-correcting process.

Aging and Intelligence

62-1 How does aging affect crystallized and fluid intelligence?

Flip It Video: Fluid & Crystallized Intelligence

With the results of cross-sectional studies showing that older adults give fewer correct answers on intelligence tests than do younger adults, WAIS-creator David Wechsler (1972) concluded that "the decline of mental ability with age is part of the general [aging] process of the organism as a whole." For a long time, this rather dismal view went unchallenged. Many corporations established mandatory retirement policies, assuming the companies would benefit by replacing aging workers with younger, more capable employees. As the saying goes, you can't teach an old dog new tricks.

FYI

Like older people, older gorillas process information more slowly (Anderson et al., 2005).

After colleges in the 1920s began giving intelligence tests to entering students, several psychologists saw their chance to study intelligence *longitudinally*. They retested the same **cohort**—the same group of people—over a period of years (Schaie & Geiwitz, 1982). What they found was a surprise: Until late in life, intelligence remained stable. On some tests, scores even increased, due partly to experience with the tests (Salthouse, 2014) (**Figure 62.1**).

cohort

a group of people sharing a common characteristic, such as from a given time period.

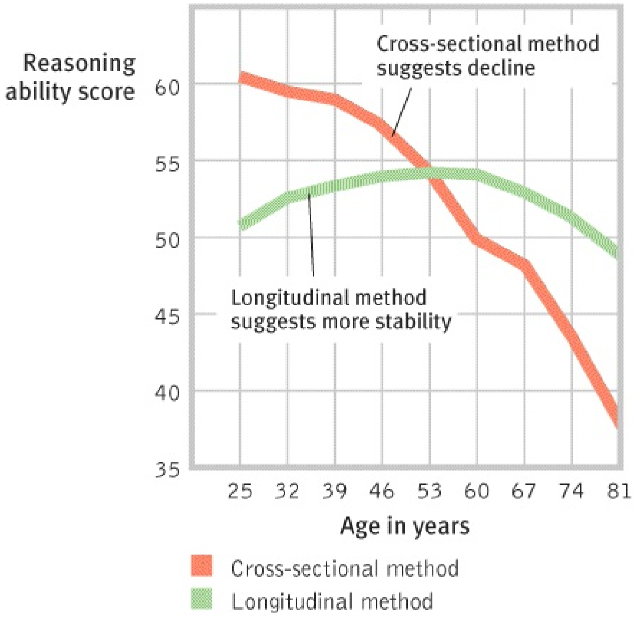

Figure 62.1
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from Schaie, 1994.

Figure 62.1 Cross-sectional versus longitudinal testing of intelligence at various ages

In this test of one type of verbal intelligence (inductive reasoning), the cross-sectional method showed declining scores with age. The longitudinal method (in which the same people were retested over a period of years) showed a slight rise in scores well into adulthood.

The more optimistic results from longitudinal studies challenged the presumption that intelligence sharply declines with age. Famed painter Anna Mary Robertson Moses ("Grandma Moses") took up painting in her seventies, and at age 88 a popular magazine named her "Young Woman of the Year." At age 89, architect Frank Lloyd Wright designed New York City's Guggenheim Museum. As the saying goes, you're never too old to learn.

So the answers to our age-and-intelligence questions depend on what we assess and how we assess it. **Crystallized intelligence**—our accumulated knowledge as reflected in vocabulary and analogies tests—increases up to old age. **Fluid intelligence**—our ability to reason speedily and abstractly, as when solving novel logic problems—decreases beginning in the twenties and thirties, slowly up to age 75 or so, then more rapidly, especially after age 85 (Deary & Ritchie, 2016; Horn, 1982; Salthouse, 2009; 2013). With age, we lose and we win. We lose recall memory and processing speed, but we gain vocabulary and knowledge (Ackerman, 2014; **Figure 62.2**). Fluid intelligence may decline, but older adults' social reasoning skills increase, as shown by an ability to take multiple perspectives, to appreciate knowledge limits, and to offer helpful wisdom in times of social conflict (Grossmann et al., 2010). Decisions also become less distorted by negative emotions such as anxiety, depression, and anger (Blanchard-Fields, 2007; Carstensen & Mikels, 2005).

crystallized intelligence

our accumulated knowledge and verbal skills; tends to increase with age.

fluid intelligence

our ability to reason speedily and abstractly; tends to decrease with age, especially during late adulthood.

cross-sectional study

research that compares people of different ages at the same point in time.

longitudinal study

research that follows and retests the same people over time.

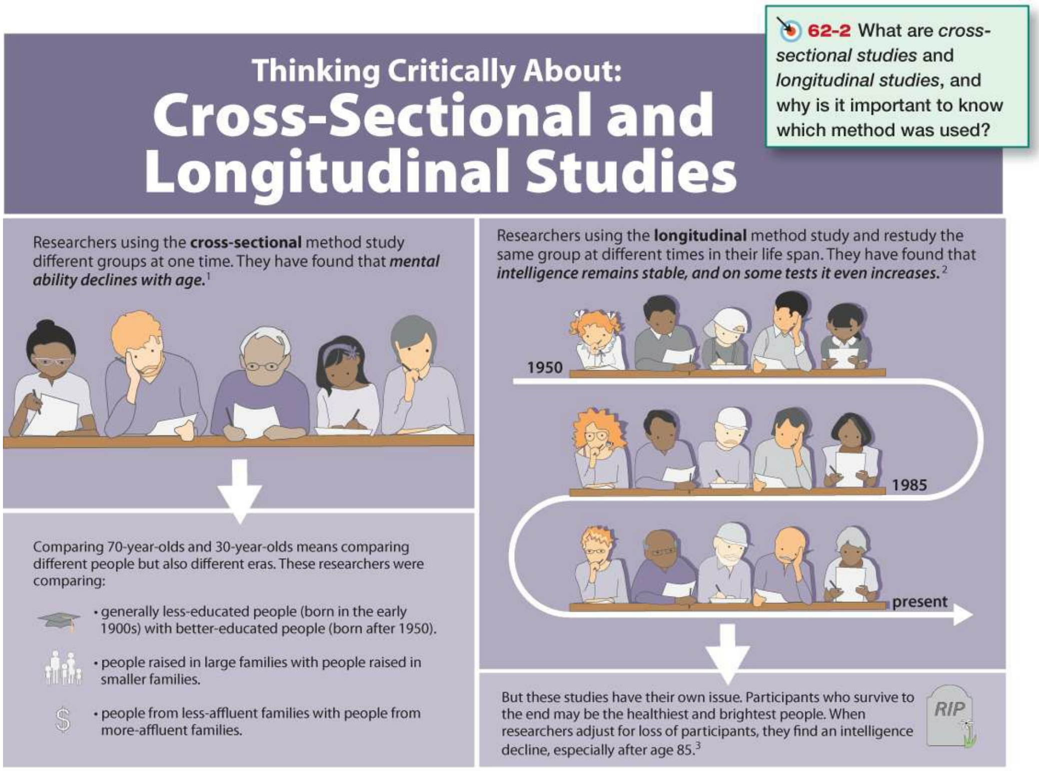
Figure 62.2 With age, we lose and we win

Studies reveal that word power grows with age, while fluid intelligence declines.

> *"Knowledge is knowing a tomato is a fruit; wisdom is not putting it in a fruit salad."*
>
> *Anonymous*

62-2 What are *cross-sectional studies* and *longitudinal studies*, and why is it important to know which method was used?



Thinking Critically About:
Cross-Sectional and Longitudinal Studies

Researchers using the **cross-sectional** method study different groups at one time. They have found that ***mental ability declines with age.***[1]

Comparing 70-year-olds and 30-year-olds means comparing different people but also different eras. These researchers were comparing:

- generally less-educated people (born in the early 1900s) with better-educated people (born after 1950).
- people raised in large families with people raised in smaller families.
- people from less-affluent families with people from more-affluent families.

Researchers using the **longitudinal** method study and restudy the same group at different times in their life span. They have found that ***intelligence remains stable, and on some tests it even increases.***[2]

But these studies have their own issue. Participants who survive to the end may be the healthiest and brightest people. When researchers adjust for loss of participants, they find an intelligence decline, especially after age 85.[3]

1. Wechsler, 1972. 2. Salthouse, 2010, 2014; Schaie & Geiwitz, 1982. 3. Brayne et al., 1999.

Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Age-related cognitive differences help explain why older adults are less likely to embrace new technologies (Charness & Boot, 2009; Pew, 2017). These cognitive differences also help explain why mathematicians and scientists produce much of their most creative work during their late twenties or early thirties, when fluid intelligence is at its peak (Jones et al., 2014). In contrast, authors, historians, and philosophers tend to produce their best work in their forties, fifties, and beyond—after accumulating more knowledge (Simonton, 1988, 1990). Poets, for example, who depend on fluid intelligence, reach their peak output earlier than prose authors, who need the deeper knowledge reservoir that accumulates with age. This finding holds across literary traditions, for both living and dead languages.

AP® EXAM TIP

Students tend to confuse crystallized and fluid intelligence. Be able to identify examples of each and whether they generally increase or decrease with age. It might help you to think about how crystals grow larger over time, as does our knowledge (crystallized intelligence).

Stability Over the Life Span

62-3 How stable are intelligence test scores over the life span?

What about the stability of early-life intelligence scores? For most children, casual observation and intelligence tests before age 3 only modestly predict their future aptitudes (Humphreys & Davey, 1988; Tasbihsazan et al., 2003). Even Albert Einstein was once thought “slow”—as he was in learning to talk (Quasha, 1980).

> “*In youth we learn, in age we understand.*”
>
> *Marie Von Ebner-Eschenbach,* Aphorisms, *1883*

By age 4, however, children’s performance on intelligence tests begins to predict their adolescent and adult scores. The consistency of scores over time increases with the age of the child (Tucker-Drob & Briley, 2014). By age 11, the stability becomes impressive, as Ian Deary and his colleagues (2004, 2009b, 2013) discovered. Their amazing longitudinal studies have been enabled by their country, Scotland, doing something that no nation has done before or since. On June 1, 1932, essentially every child in the country born in 1921—87,498 children around age 11—took an intelligence test. The aim was to identify working-class children who would benefit from further education. Sixty-five years later to the day, Patricia Whalley, the wife of Deary's co-worker, Lawrence Whalley, discovered the test results on dusty storeroom shelves at the Scottish Council for Research in Education, not far from Deary's Edinburgh University office. "This will change our lives," Deary replied when Whalley told him the news.

> “*My dear Adele, I am 4 years old and I can read any English book. I can say all the Latin substantives and adjectives and active verbs besides 52 lines of Latin poetry.*”
>
> *Francis Galton, letter to his sister, 1827*

And so it has, with dozens of studies of the stability and the predictive capacity of these early test results. For example, when the intelligence test administered to 11-year-old Scots in 1932 was readministered to 542 survivors as turn-of-the-millennium 80-year-olds, the correlation between the two sets of scores—after nearly 70 years of varied life experiences—was striking (**Figure 62.3**). Ditto when 106 survivors were retested at age 90 (Deary et al., 2013). Another study that followed Scots born in 1936 from ages 11 to 70 confirmed the remarkable stability of intelligence, independent of life circumstance (Johnson et al., 2010).

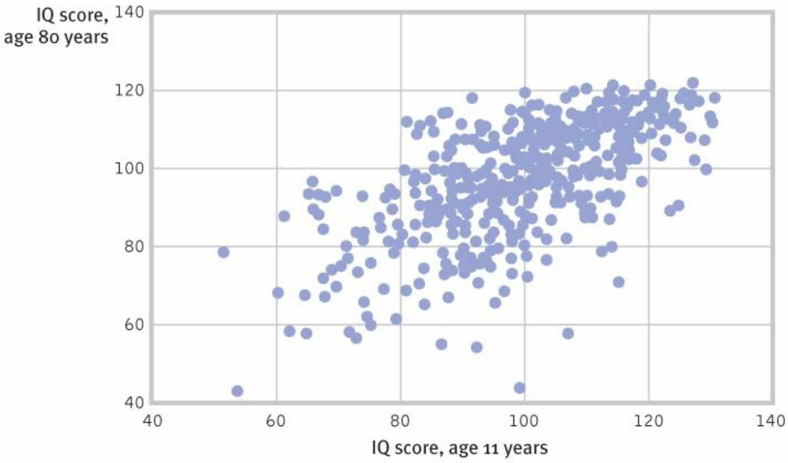


Figure 62.3
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from Deary et al., 2004.

Figure 62.3 Intelligence endures

When Ian Deary and his colleagues retested 80-year-old Scots using an intelligence test they had taken as 11-year-olds, their scores across seven decades correlated +0.66, as shown here. When 106 survivors were again retested at age 90, the correlation with their age 11 scores was +0.54 (Deary et al., 2013).

Children and adults who are more intelligent also tend to live healthier and longer lives (**Figure 62.4**). Why might this be the case? Deary (2008) reports four possible explanations:

1. Intelligence facilitates more education, better jobs, and a healthier environment.
2. Intelligence encourages healthy living: less smoking, better diet, more exercise.
3. Prenatal events or early childhood illnesses might have influenced both intelligence and health.
4. A "well-wired body," as evidenced by fast reaction speeds, perhaps fosters both intelligence and longevity. (Intelligent people tend to be literally quick-witted—to perceive and respond to stimuli quickly.)

Extremes of Intelligence

62-4 What are the traits of those at the low and high intelligence extremes?

One way to glimpse the validity and significance of any test is to compare people who score at the two extremes of the normal curve. The two groups should differ noticeably, and on intelligence tests, they do.

The Low Extreme

Intellectual disability (formerly called *mental retardation*) is a developmental condition that is apparent before age 18, sometimes with a known physical cause. (**Down syndrome**, for example, is a disorder of varying intellectual and physical severity caused by an extra copy of chromosome 21 in the person's genetic makeup.) To be diagnosed with an intellectual disability, a person must meet two criteria. The first is low intellectual functioning as reflected in a low intelligence test score. Guidelines specify test score performance that is in the lowest 3 percent of the general population, or about 70 or below (Schalock et al., 2010). The second criterion is that the person must have difficulty adapting to the normal demands of independent living, as expressed in three areas, or skills: *conceptual* (language, reading, and concepts of money, time, and number), *social* (interpersonal skills, being socially responsible, following basic rules and laws, avoiding being victimized), and *practical* (health and personal care, occupational skill, and travel). In mild forms, intellectual disability, like normal intelligence, results from a combination of genetic and environmental factors (Reichenberg et al., 2016).

intellectual disability

a condition of limited mental ability, indicated by an intelligence test score of 70 or below and difficulty adapting to the demands of life. (Formerly referred to as *mental retardation*.)

Down syndrome

a condition of mild to severe intellectual disability and associated physical disorders caused by an extra copy of chromosome 21.

Claudia Daut/Reuters/Newscom

Mainstreaming in Chile Most Chilean children with Down syndrome have attended separate schools for children with special needs. However, this boy is a student at the Altamira School, where children with differing abilities share the classrooms.

When, thanks to the *Flynn effect*, intelligence tests are periodically restandardized, the intellectual-disability test score boundary can shift. Depending on when they were tested, two people with the same ability level could be classified differently (Kanaya et al., 2003; Reynolds et al., 2010). After one restandardization, individuals who scored near 70 on earlier tests suddenly lost about 6 test score points. As this has occurred, more people have become eligible for special education and financial assistance.

For some, intelligence test scores can mean life or death. In the United States (one of the only industrialized countries with the death penalty), the Flynn effect means fewer Americans are now eligible for execution: The U.S. Supreme Court ruled in 2002 that the execution of people with an intellectual disability—defined as a test score of below 70—is “cruel and unusual punishment.” For Teresa Lewis, that cutoff was high stakes. Lewis, a “dependent personality” with limited intellect, allegedly agreed to a plot in which two men killed her husband and stepson in exchange for a split of a life insurance payout (Eckholm, 2010). With a reported test score of 72, the State of Virginia executed Lewis in 2010. If only she had scored 69.

In 2014, the U.S. Supreme Court recognized the imprecision and arbitrariness of a fixed cutoff score of 70, and required states with death row inmates who have scored just above 70 to consider other evidence. Thus, Ted Herring, who had scored 72 and 74 on intelligence tests—but without knowing that summer follows spring or how to transfer between buses—was taken off Florida's death row (Alvarez & Schwartz, 2014).

FYI

Terman did test two future Nobel laureates in physics, but they failed to score above his gifted sample cutoff (Hulbert, 2005).

The High Extreme

Children whose intelligence test scores indicate extraordinary academic gifts mostly thrive. In one famous project begun in 1921, Lewis Terman studied more than 1500 California schoolchildren with IQ scores over 135. These high-scoring children (later called the "Termites"), like those in later studies, were healthy, well-adjusted, and unusually successful academically (Friedman & Martin, 2012; Koenen et al., 2009; Lubinski, 2009, 2016). When restudied over the next seven decades, most people in Terman's group had attained high levels of education (Austin et al., 2002; Holahan & Sears, 1995). Many were doctors, lawyers, professors, scientists, and writers, though none were Nobel Prize winners.

FYI

Among the high-scoring whiz kids in national searches for precocious youth were Google co-founder Sergey Brin, Facebook's Mark Zuckerberg, and musician Stefani Germanotta (Lady Gaga) (Clynes, 2016). Another became a professional poker player with $100,000+ annual earnings (Lubinski, 2016).

Other studies have followed the lives of precocious youths who had aced the math SAT at age 13—by scoring in the top 1 percent of their age group. By their fifties, these 1650 math whizzes had secured 681 patents (Lubinski et al., 2014). Another group of 13-year-old verbal aptitude high scorers were, by age 38, twice as likely as the math aces to have become humanities professors or written a novel (Kell et al., 2013). About 1 percent of Americans earn doctorates. But for the 12- and 13-year-olds who scored in the top 1 in 10,000 among those of their age taking the SAT, about 4 in 10 had done so (Kell et al., 2013; Makel et al., 2016). One of psychology's whiz kids was Jean Piaget, who by age 15 was publishing scientific articles on mollusks and who went on to become the twentieth century's most famous developmental psychologist (Hunt, 1993).

Is there a gifted education program at your school? "Gifted child" programs tend to segregate high-scoring children in special classes, giving them academic enrichment not available to their peers. Critics note that tracking by aptitude sometimes creates a self-fulfilling prophecy: Implicitly labeling some children as "ungifted" and denying them opportunities for enriched education can widen the achievement gap between ability groups (Lipsey & Wilson, 1993; Stevenson & Lee, 1990). Because minority and low-income youth are more often placed in lower academic groups, tracking can also promote segregation and prejudice—hardly, note critics, a healthy preparation for working and living in a multicultural society.

MATHEMATICAL SCIENCE BUILDING

JOE KLAMAR/Getty Images

The extremes of intelligence Moshe Kai Cavalin completed his third college degree by the time he was 14, when the math major graduated from UCLA.

According to his mother, he first picked up a college textbook and started reading it at age 2.

Critics and proponents of gifted education do, however, agree on this: Children have differing gifts, whether at math, verbal reasoning, art, or social leadership. Some children exhibit exceptional potential or talent in a given domain. Educating children as if all were alike is as naive as assuming that giftedness is something, like blue eyes, that you either have or do not have. One need not stick labels on children to affirm their special talents and to challenge them all at the frontiers of their own ability and understanding. By providing *appropriate placement* suited to each child's talents (as when allowing a math whiz to study math at a higher level), we can promote both equity and excellence for all (Subotnik et al., 2011).

✓ Check Your Understanding

Ask Yourself

- How do you feel about placing children of all ability levels in the same classroom? What evidence are you using to support your view?

Test Yourself

- Researcher A is well-funded to learn about how intelligence changes over the life span. Researcher B wants to study the intelligence of people who are now at various life stages. Which researcher should use the cross-sectional method, and which the longitudinal method?
- Why do psychologists not diagnose an intellectual disability based solely on a person's intelligence test score?
- The Smiths have enrolled their 2-year-old son in a special program that promises to assess his IQ and, if he places in the top 5 percent of test-takers, to create a plan that will guarantee his admission to a top university at age 18. Why is this endeavor of questionable value?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 62 REVIEW

62-1 How does aging affect crystallized and fluid intelligence?

- Cross-sectional studies and longitudinal studies have shown that *fluid intelligence* declines in older adults, in part because neural processing slows. *Crystallized intelligence* tends to increase.

62-2 What are *cross-sectional studies* and *longitudinal studies*, and why is it important to know which method was used?

- *Cross-sectional studies* compare people of different ages at the same point in time. *Longitudinal studies* follow and retest the same *cohort* over a period of years.
- Cross-sectional studies also compare people of different eras and life circumstances. This can provide an excellent snapshot of a particular point in time, but longitudinal studies are better equipped to trace the evolution of traits over a longer time period.

62-3 How stable are intelligence test scores over the life span?

- The stability of intelligence test scores increases with age.
  - At age 4, scores fluctuate somewhat but begin to predict adolescent and adult scores.
  - By early adolescence, scores are very stable and predictive.

62-4 What are the traits of those at the low and high intelligence extremes?

- An intelligence test score of or below 70 is one diagnostic criterion for the diagnosis of *intellectual disability* (others are limited conceptual, social, and practical skills).

- *Down syndrome*, a developmental disorder caused by an extra copy of chromosome 21, is one known physical cause of intellectual disability.
- High-scoring people tend to be healthy and well-adjusted, as well as unusually successful academically.
    - Schools sometimes “track” such children, separating them from students with lower scores. Such programs can become self-fulfilling prophecies as both groups live up to—or down to—others’ perceptions and expectations.

Multiple-Choice Questions

1. Which of the following is a longitudinal study?

   a. Researchers test the intelligence of all the students in a high school.
   b. Intelligence tests are given to the residents of a nursing home.
   c. Researchers randomly select 50 students from a high school with 2000 students. The 50 students are given intelligence tests.
   d. A group of college juniors is given an extensive battery of tests over a period of 2 days.
   e. A group of kindergartners is given an intelligence test. They are retested every other year for 30 years.

2. Which of the following best represents crystallized intelligence?

   a. Jake can solve math word problems quickly.
   b. Grandpa Milt is good at crossword puzzles.
   c. Aliyah has a knack for training dogs.
   d. Anna writes creative computer programs.
   e. Heng takes a different route each day on his walk.

3. Hal scored an 89 on an intelligence test when he was 16. Now, at age 56, he is interested in what his score would be as an adult. The score he is most likely to earn on the new test would be

   a. 49.
   b. 70.
   c. 92.

d. 129.
e. 140.

4. Intellectual disability is defined by both IQ and which of the following?

a. Chronological age
b. Mental age
c. Adaptive ability
d. Physical condition
e. Heritability

Practice FRQs

1. Describe how each of the following types of evidence are used to determine whether there is an intellectual decline as people age.

- Evidence from cross-sectional studies
- Evidence from longitudinal studies

Answer

2 points: Cross-sectional studies would test people from several age groups at once. This type of study would examine a group of younger people and a group of older people at one point in time and compare their test scores to see if those in the older group had lower scores. Page 641

2 points: Longitudinal studies would test the same group of people periodically over a long period of time. This type of study would compare individuals’ test scores at varying ages to see if there is a decline as the participants grow older. Page 641

2. Provide three pieces of evidence that explain why more intelligent people might live longer.

(3 points)

Module 63 Studying Genetic and Environmental Influences on Intelligence

LEARNING TARGETS

- 63-1 Analyze the evidence for a genetic influence on intelligence, and explain what is meant by *heritability*.
- 63-2 Analyze the evidence for environmental influences on intelligence.

Intelligence runs in families. But why? Are our intellectual abilities mostly inherited? Or are they molded by our environment? Few issues arouse so much passion. If we mainly inherit our intelligence, then people’s socioeconomic standing will correspond to their inborn differences. But if intelligence is mainly nurtured by our environments, then children from disadvantaged backgrounds can expect to lead disadvantaged lives—but with some hope that changing the environment could produce more intelligent and accomplished adults. Let’s examine some of the evidence.

Twin and Adoption Studies

63-1 What evidence points to a genetic influence on intelligence, and what is *heritability*?

Do people who share the same genes also share mental abilities? As you can see from **Figure 63.1**, which summarizes many studies, the answer is clearly *Yes*. Consider:

- The intelligence test scores of identical twins raised together are nearly as similar as those of the same person taking the same test twice (Haworth et al., 2009; Lykken, 2006; Plomin et al., 2016). (The scores of fraternal twins, who share only about half their genes, differ more.) Estimates of the **heritability** of intelligence—the extent to which intelligence test score variation within a group can be attributed to genetic variation—range from 50 to 80 percent (Madison et al., 2016; Plomin et al., 2016). Identical twins also exhibit substantial similarity (and heritability) in specific talents, such as music, math, and sports. Heredity accounts for more than half the variation in the national math and science exam scores of British 16-year-olds (Shakeshaft et al., 2013; Vinkhuyzen et al., 2009).
- Scans reveal that identical twins' brains have similar gray- and white-matter volume, and the areas associated with verbal and spatial intelligence are virtually the same (Deary et al., 2009a; Thompson et al., 2001). Their brains also show similar activity while doing mental tasks (Koten et al., 2009).
- Are there known genes for genius? When 200 researchers pooled their data on 126,559 people, all of the gene variations analyzed accounted for only about 2 percent of the differences in educational achievement (Rietveld et al., 2013, 2014). This result was not a fluke; others have replicated this modest effect of genes on educational achievement (Belsky et al., 2016). And using a new genetic method, a follow-up British study recently found genes that predicted 9 percent of the

variation in school achievement at age 16 (Selzam et al., 2016). This much seems clear: *Intelligence is polygenetic*, involving many genes. Wendy Johnson (2010) likens the polygenetic effect to height: 54 specific gene variations together account for 5 percent of our individual height differences, leaving the rest yet to be discovered. What matters for intelligence—as for height, personality, sexual orientation, schizophrenia or just about any human trait—is the combination of many genes (Plomin et al., 2016).

Figure 63.1 Intelligence: Nature and nurture

The most genetically similar people have the most similar intelligence scores. Remember: 1.00 indicates a perfect correlation; zero indicates no correlation at all.

Donald Reilly The New Yorker Collection
/The Cartoon Bank

“I told my parents that if grades were so important they should have paid for a smarter egg donor.”

heritability
the proportion of variation among individuals in a group that we can attribute to genes. The heritability of a trait may vary, depending on the range of populations and environments studied.

Other evidence points to environment effects:

- Where environments vary widely, as they do among children of less-educated parents, environmental differences are more predictive of intelligence scores (Tucker-Drob & Bates, 2016).
- Adoption enhances the intelligence scores of mistreated or neglected children (van IJzendoorn & Juffer, 2005, 2006). So does adoption from poverty into middle-class homes (Nisbett et al., 2012). In one large Swedish study, children adopted into wealthier families with more educated parents had IQ scores averaging 4.4 points higher than their not-adopted biological siblings (Kendler et al., 2015).
- The intelligence scores of “virtual twins”—same-age, unrelated siblings adopted as infants and raised together—correlate +0.28 (Segal et al., 2012). This suggests a modest influence of their shared environment.

AP® EXAM TIP

Figure 63.1 is worth spending some time on. Try grabbing a study buddy and explaining whether each of the five conditions provides more support for nature or more for nurture. In most cases, it’s some of each and you have to look at comparisons between categories to really be able to draw conclusions.

Seeking to disentangle genes and environment, researchers have also compared the intelligence test scores of adopted children with those of (a) their *biological parents* (the providers of their genes) and (b) their *adoptive parents* (the providers of their home environment). Over time, adopted children accumulate experience in their differing adoptive families. So, would you expect the family-environment effect to grow with age and the genetic-legacy effect to shrink?

If you would, behavior geneticists have a stunning surprise for you. Mental similarities between adopted children and their adoptive families wane with age (McGue et al., 1993). Adopted children's intelligence scores resemble those of their biological parents much more than their adoptive parents (Loehlin, 2016). Genetic influences—not environmental ones—become more apparent as we accumulate life experience. Identical twins' similarities, for example, continue or increase into their eighties. Thus, report Ian Deary and his colleagues (2009a, 2012), the heritability of general intelligence increases from "about 30 percent" in early childhood to "well over 50 percent in adulthood." In one massive study of 11,000 twin pairs in four countries, the heritability of general intelligence (*g)* increased from 41 percent in middle childhood to 55 percent in adolescence to 66 percent in young adulthood (Haworth et al., 2010). Similarly, adopted children's verbal ability scores over time become more like those of their biological parents (**Figure 63.2**). Who would have guessed?

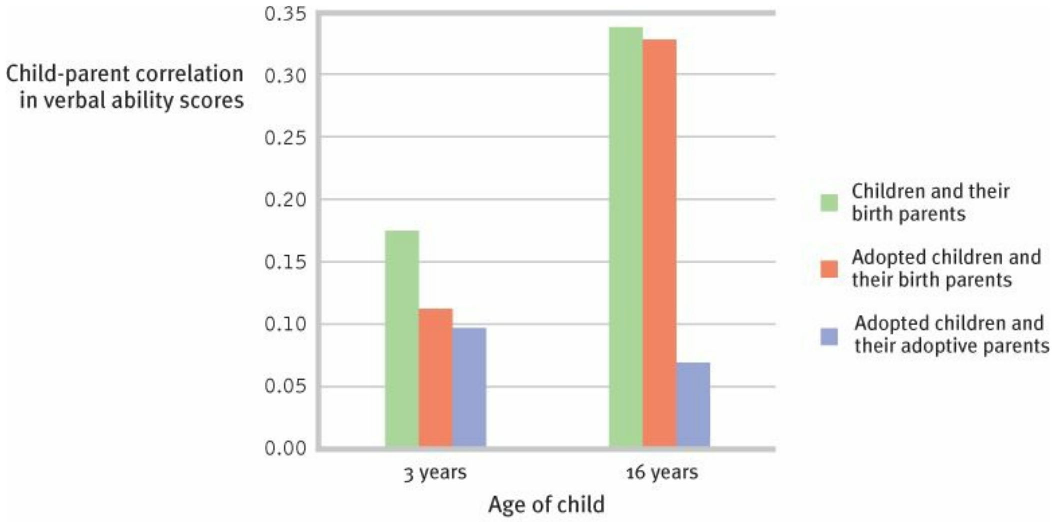

Figure 63.2

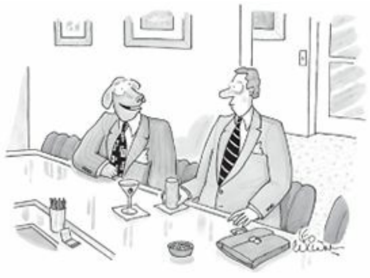
Data from Plomin & DeFries, 1998.

Figure 63.2 In verbal ability, whom do adopted children resemble?

As the years went by in their adoptive families, children's verbal ability scores became more like their *biological* parents' scores.



Leo Cullum/The New Yorker Collection/The Cartoon Bank

"Selective breeding has given me an aptitude for the law, but I still love fetching a dead duck out of freezing water."

Environmental Influences

63-2 What does evidence reveal about environmental influences on intelligence?

Genes matter. Even if we were all raised in the same intellectually stimulating environment, we would have differing aptitudes. But life experiences also matter. Human environments are rarely as impoverished as the dark and barren cages inhabited by deprived rats that develop thinner-than-normal brain cortexes (Rosenzweig, 1984; see Module 50). Yet severe deprivation also leaves footprints on the human brain.

Early Environmental Influences

Nowhere is the intertwining of biology and experience more apparent than in the most hopeless human environments, such as J. McVicker Hunt (1982) observed in a destitute Iranian orphanage. The typical child Hunt observed there could not sit up unassisted at age 2 or walk at age 4. The little care the infants received was not in response to their crying, cooing, or other behaviors, so the children developed little sense of personal control over their environment. They were instead becoming passive "glum lumps." Extreme deprivation was bludgeoning native intelligence—a finding confirmed by studies of children raised in poorly run orphanages in Romania and elsewhere (Nelson et al., 2009, 2013; van IJzendoorn et al., 2008).

Josef Polleross/The Image Works

Devastating neglect Some Romanian orphans, such as this child in the

Leaganul Pentru Copii orphanage in 1990, had minimal interaction with caregivers and suffered delayed development.

Aware of both the dramatic effects of early experiences and the impact of early intervention, Hunt began a training program for the Iranian caregivers, teaching them to play language-fostering games with 11 infants. They imitated the babies' babbling, engaged them in vocal follow-the-leader, and, finally, they taught the infants sounds from the Persian language. The results were dramatic. By 22 months of age, the infants could name more than 50 objects and body parts, and so charmed visitors that most were adopted—an unprecedented success for the orphanage.

Hunt's findings are an extreme case of a more general finding: Poor environmental conditions can depress cognitive development. Schools with many poverty-level children often have less-qualified teachers, as one study of 1450 Virginia schools found (Tuerk, 2005). And these factors predicted lower achievement scores.

Poverty-related stresses also impede cognitive *performance* (Heberle & Carter, 2015). Like a computer that slows when running multiple operations, impoverished people's worries and distractions consume cognitive bandwidth and can diminish their thinking capacity. For example, on tests of cognitive functioning, sugar cane farmers in India scored better after being paid for their harvest—when their money worries dropped (Mani et al., 2013). Poverty can deplete cognitive capacity.

So, extreme conditions—sensory deprivation, social isolation, poverty—can slow normal brain development. Is the reverse also true? Will an "enriched" environment give children a superior intellect? Most experts are doubtful (Bruer, 1999; DeLoache et al., 2010; Reichert et al., 2010). There is no environmental recipe for fast-forwarding a normal infant into a genius. All babies should have normal exposure to sights, sounds, and speech. Although preschool experiences matter, Sandra Scarr's (1984) verdict still is widely shared: "Parents who are very concerned about providing special educational lessons for their babies are wasting their time."

Schooling and Intelligence

Early Intervention

Later in childhood, schooling is one intervention that pays intelligence score dividends. Schooling and intelligence interact, and both enhance later income (Ceci & Williams, 1997, 2009). Hunt was a strong believer in the ability of education to boost children’s chances for success by developing their cognitive and social skills. Indeed, his 1961 book, *Intelligence and Experience*, helped launch Project Head Start in 1965, a U.S. government-funded preschool program that has served more than 30 million children, most of whom come from families below the poverty level (Head Start, 2013). Does it succeed? Studies suggest that Head Start increases school readiness and gives a modest boost to later health and high school completion rate (Deming, 2009; Mervis, 2011; Pianta et al., 2009). Generally, however, aptitude benefits fade out over time (reminding us that life experiences *after* Head Start matter, too).

More encouraging results come from intensive post-babyhood preschool programs (Dodge et al., 2017; Garcia et al., 2016; Tucker-Drob, 2012). Across a number of experiments, intelligence scores also rise with nutritional supplements to pregnant mothers and newborns (3.5 points), with quality preschool experiences (4 points), and with interactive reading programs (6 points) (Protzko et al., 2013).

Genes and experience together weave the fabric of intelligence. (Recall from Module 14 that *epigenetics* is one field that studies this nature–nurture meeting place.) But what we accomplish with our intelligence depends also on our own beliefs and motivation. One analysis of 72,431 undergraduates found that study motivation and study skills rivaled aptitude and previous grades as predictors of academic achievement (Credé & Kuncel, 2008). Motivation can even affect intelligence test performance. Four dozen studies show that, when promised money for doing well, adolescents score higher on such tests (Duckworth et al., 2011).

Growth Mindset

These observations would not surprise psychologist Carol Dweck (2006, 2015a,b, 2016). She reports that believing intelligence is changeable, not fixed, fosters a *growth mindset,* a focus on learning and growing. Dweck teaches young teens that the brain is like a muscle, growing stronger with use as neuron connections grow: “Learning how to do a new kind of problem grows your math brain!” Receiving praise for *effort and for tackling challenges,* rather than being smart or accomplished, helps teens understand the link between hard work and success (Gunderson et al., 2013). They also become more resilient when others frustrate them (Paunesku et al., 2015; Yeager et al., 2013, 2014, 2016a). Indeed, superior achievements in fields from sports to science to music arise from the combination of ability, opportunity, and disciplined effort (Ericsson et al., 2007).

> “*It is our choices . . . that show what we truly are, far more than our abilities.*”
>
> *Professor Dumbledore to Harry Potter in J. K. Rowling’s* Harry Potter and the Chamber of Secrets, *1999*

More than 300 studies confirm that ability + opportunity + motivation = success. Extremely high intelligence-test-scoring 12-year-olds are much more likely than the average person to later earn doctorates and hold patents—if their ability is “coupled with commitment” (Makel et al., 2016). High school students’ math proficiency and college students’ grades reflect their aptitude but also their self-discipline, their belief in the power of effort, and a curious, “hungry mind” (Murayama et al., 2013; Richardson et al., 2012; von Stumm et al., 2011). In a study of 168,000 Chilean tenth graders, those from the lowest-income families who had a growth mindset had academic test scores comparable to high-income students who had a fixed mindset (Claro et al., 2016). And consider: South Asian–Americans won all nine U.S. national spelling bee contests between 2008 and 2016, an incredible achievement likely influenced by a cultural belief that strong effort will bring success (Rattan et al., 2012; Shankar, 2016).

Dave Nagel/Getty Images

A hungry mind

Alex Wong/Getty Images

U.S. spelling champs Nihar Janga, 11, and Jairam Hathwar, 13, celebrate their co-winning the 2016 Scripps National Spelling Bee. What were Nihar and Jairam’s winning words? “Gesellschaft” and “Feldenkrais.”

These repeated findings—that a growth mindset and disciplined effort enhance achievement—have generated media attention and encouraged large-scale interventions with at-risk students. One downside, caution some researchers, is a possible overemphasis on positive thinking’s power to lift people out of disadvantage. Doing so comes at a social cost—blaming struggling individuals for their circumstances (Ikizer & Blanton, 2016). Sometimes people need more than the power of positive thinking to overcome their harsh conditions.

✓ Check Your Understanding

Ask Yourself

- How have genetic and environmental influences shaped your intelligence?

Test Yourself

- A check on your understanding of heritability: If environments become more equal, the heritability of intelligence will
  - a. increase.
  - b. decrease.
  - c. be unchanged.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 63 REVIEW

63-1 What evidence points to a genetic influence on intelligence, and what is *heritability?*

- Studies of twins, family members, and adoptees indicate a significant hereditary contribution to intelligence scores.
- Intelligence seems to be polygenetic, and researchers are searching for genes that exert an influence.
- *Heritability* is the proportion of variation among individuals that can be attributed to genes.

63-2 What does evidence reveal about environmental influences on intelligence?

- Studies of twins, family members, and adopted children provide evidence of environmental influences.
- Test scores of identical twins raised apart are slightly less similar (though still very highly correlated) than the scores of identical twins raised together.
- Studies of children raised in extremely impoverished environments with minimal social interaction indicate that life experiences can significantly influence intelligence test performance.
- No evidence supports the idea that normal, healthy children can be molded into geniuses by growing up in an exceptionally enriched environment.

Multiple-Choice Questions

1. Heritability relates to the

a. percentage of a person’s intelligence that is due to environmental influences.

b. percentage of a person’s intelligence that is due to genetics.
c. correlation of intelligence test scores among family members.
d. extent to which variability among individuals’ intelligence scores can be attributed to genetic variation.
e. genetic stability of intelligence over time.

2. There is a greater correlation between the IQ scores of identical twins raised together than for fraternal twins raised together. What conclusion can be drawn from this data?

a. There is no significant hereditary contribution to intelligence.
b. There is no significant environmental contribution to intelligence.
c. There is no significant genetic or environmental effect on intelligence.
d. There is a genetic effect on intelligence.
e. There is an environmental effect on intelligence.

3. Which of the following is true of the mental similarities between adoptive children and their adoptive parents over time?

a. Adoptive children become much more similar to their adoptive parents over time.
b. Adoptive children become slightly more similar to their adoptive parents over time.
c. There is hardly any similarity when the adoptive children are young or when they are older.
d. Adoptive children become slightly less similar to their adoptive parents over time.
e. Adoptive children become much less similar to their adoptive parents over time.

4. According to Carol Dweck, students are often hampered by a “fixed mindset.” This means they believe:

a. intelligence is biologically set and unchangeable.
b. it is never good to change your mind once it is made up.
c. intelligence is changeable.
d. they have already done everything they can to improve.

e. problems can only be solved in a particular way.

Practice FRQs

1. Explain whether each of the following comparisons demonstrates the influence of genetics or of environment on intelligence.

- The correlation of intelligence test scores for identical twins raised *together* is about +.85. For identical twins raised *apart*, the correlation is about +.72.
- The correlation of intelligence test scores for identical twins raised together is about +.85. For fraternal twins raised together, it is about +.60.

Answer

1 point: The first comparison demonstrates the influence of environment. The people being studied were genetically identical twins in both cases, so the higher correlation for identical twins raised together must be due to environment. Page 647

1 point: The second comparison demonstrates the influence of genetics. In both cases, the twins being studied were raised in the same environment, so the higher correlation for identical twins must be due to the fact that there is more genetic similarity between identical twins than between fraternal twins. Page 647

2. Explain two environmental interventions that can help children develop better cognitive skills.

(2 points)

Module **64 Group Differences and the Question of Bias**

LEARNING TARGETS

- 64-1 Examine how and why the genders differ in mental ability scores.
- 64-2 Examine how and why racial and ethnic groups differ in mental ability scores.
- 64-3 Discuss whether intelligence tests are inappropriately biased, and explain the influence of stereotype threat on test-takers' performance.

Group Differences in Intelligence Test Scores

If there were no group differences in aptitude scores, psychologists would have less debate over hereditary and environmental influences. But there are group differences. What are they? And what shall we make of them?

Gender Similarities and Differences

64-1 How and why do the genders differ in mental ability scores?

In science as in everyday life, it is differences, not similarities, that excite interest. In worldwide studies, men estimate their own intelligence higher than do females (Furnham, 2016). Yet compared with the anatomical and physiological differences between men and women, our intelligence differences are minor. In that 1932 testing of all Scottish 11-year-olds, for example, girls' average intelligence score was 100.6 and boys' was 100.5 (Deary et al., 2003). So far as *g* is concerned, boys and girls, and men and women, are the same.

Yet, most people find differences more newsworthy. Girls outpace boys in spelling, verbal fluency, locating objects, detecting emotions, and sensitivity to touch, taste, and color (Halpern et al., 2007; Voyer & Voyer, 2014). Boys outperform girls in tests of spatial ability and complex math problems, though in math computation and overall math performance, boys and girls hardly differ (Else-Quest et al., 2010; Hyde & Mertz, 2009; Lindberg et al., 2010). Males' mental ability scores also vary more than females'. Thus, boys worldwide outnumber girls at both the low extreme and the high extreme (Brunner et al., 2013). Boys, for example, are more often found in special education classes, but also among those scoring very high on the SAT math test.

FYI

Give females long-term testosterone therapy (for female-to-male sex reassignment) and their brain language processing areas become, after losing some gray matter, more male-like (Hahn et al., 2016).

The most reliable male edge appears in spatial ability tests like the one shown in **Figure 64.1** (Maeda & Yoon, 2013; Palejwala & Fine, 2015). The solution requires speedy mental rotation of three-dimensional objects. Today, such skills help when fitting suitcases into a car trunk, playing chess, or doing certain types of geometry problems. From an evolutionary perspective, those same skills would have helped our ancestral fathers track prey and make their way home (Geary, 1995, 1996; Halpern et al., 2007). The survival of our ancestral mothers may have benefited more from a keen memory for the location of edible plants—a legacy that lives today in women’s superior memory for objects and their location.

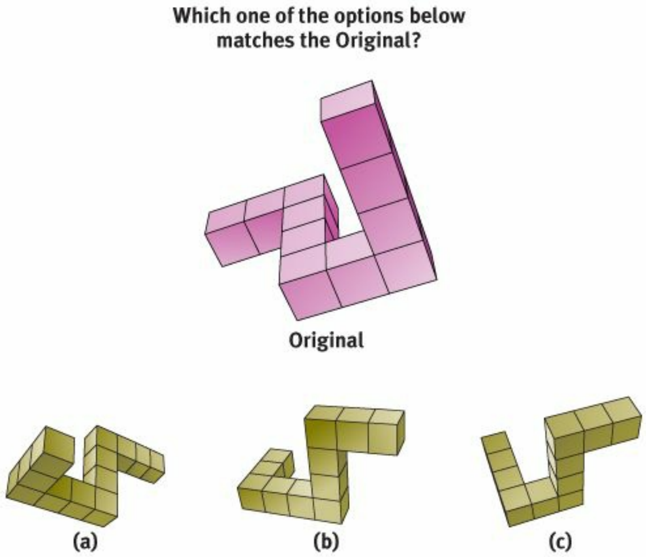


Figure 64.1

Figure 64.1 A mental rotation test

This illustrates the type of items found on a spatial abilities test. See answer below.[1]

Evolutionary psychologist Steven Pinker (2005) has argued that biology affects gender differences in life priorities (women’s somewhat greater interest in people versus men’s in money and things), in risk-taking (with men more reckless), and in math reasoning and spatial abilities. Such differences are, he noted, observed across cultures, stable over time, influenced by prenatal hormones, and observed in genetic boys raised as girls.

Maryam Mirzakhani/Getty Images

Minding the math gap In 2014, Iranian math professor Maryam Mirzakhani (1977–2017) became the first woman to win math’s most admired award, the Fields Medal. What was her advice to people who want to know more about math? Practice patience. “The beauty of mathematics,” Mirzakhani said, “only shows itself to more patient followers” (*The Guardian*, 2014).

But social influences also construct gender. Researchers report that culturally influenced preferences help explain why American women, more than men, avoid math-intensive vocations (Ceci & Williams, 2010, 2011). Social expectations and divergent opportunities also shape boys’ and girls’ interests and abilities (Crawford et al., 1995; Eccles et al., 1990). In Asia and Russia, teen girls have outperformed boys in an international science exam; in North America and Britain, boys have scored higher (Fairfield, 2012). More gender-equal cultures, such as Sweden and Iceland, exhibit little of the gender math gap found in gender-unequal cultures, such as Turkey and Korea (Guiso et al., 2008; Kane & Mertz, 2012). Since the 1970s, as gender equity has increased in the United States, the boy-to-girl ratio among 12- to 14-year-olds with very high SAT math scores (above 700) has declined from 13 to 1 to 3 to 1 (Nisbett et al., 2012). And in psychology, there’s been a dramatic change in the ratio of women to men earning doctorates—from 17 percent women in 1958 to 70 percent in 2015 (Burelli, 2008; NSF, 2016). Experience matters.

“That’s an excellent suggestion, Miss Triggs. Perhaps one of the men would like to suggest it.”

Racial and Ethnic Similarities and Differences

64-2 How and why do racial and ethnic groups differ in mental ability scores?

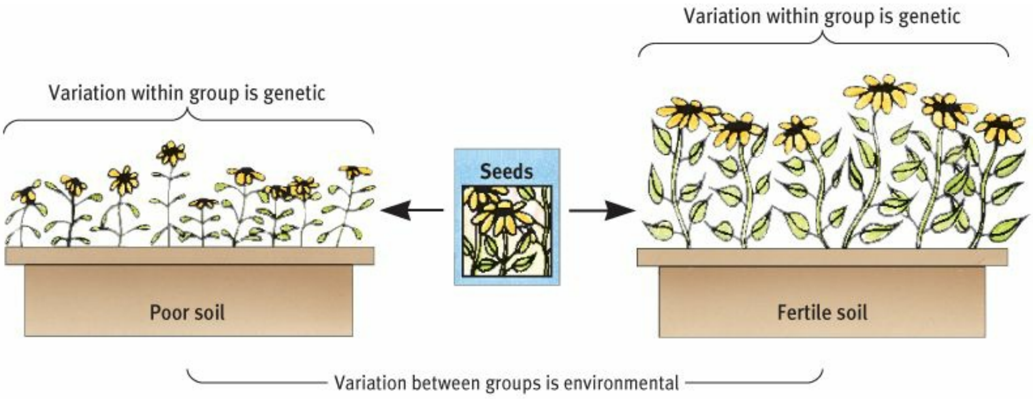
Fueling the group-differences debate are two other disturbing but scientifically agreed-upon facts:

- Racial and ethnic groups differ in their average intelligence test scores.
- High-scoring people (and groups) are more likely to attain high levels of education and income.

There are many group differences in average intelligence test scores. New Zealanders of European descent outscore native Maori New Zealanders. Israeli Jews outscore Israeli Arabs. Most Japanese outscore most Burakumin, a stigmatized Japanese minority. And White Americans have outscored Black Americans. This Black-White difference has diminished somewhat in recent years, especially among children (Dickens & Flynn, 2006; Nisbett et al., 2012). Such *group* differences provide little basis for judging individuals. Worldwide, women outlive men by four years, but knowing only that you are male or female won’t tell us how long you will live.

Larry Williams/Getty Images

We have seen that heredity contributes to *individual* differences in intelligence. But group differences in a heritable trait may be entirely environmental. Consider one of nature's experiments: Allow some children to grow up hearing their culture's dominant language, while others, born deaf, do not. Then give both groups an intelligence test rooted in the dominant language, and (no surprise) those with expertise in that language will score higher (Braden, 1994; Steele, 1990; Zeidner, 1990). Although individual performance differences may be substantially genetic, the group difference is not (**Figure 64.2**).



Variation within group is genetic
Variation within group is genetic
Seeds
Poor soil
Fertile soil
Variation between groups is environmental

Figure 64.2
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Information from Lewontin, 1976.

Figure 64.2 Group differences and environmental impact

Even if the variation between members within a group reflects genetic differences, the average difference between groups may be wholly due to environment. Imagine that seeds from the same mixture are sown in different soils. Although height differences *within* each window box of flowers will be genetic, the height difference *between* the two groups will be environmental.

Might the racial gap be similarly environmental? Consider:

Genetics research reveals that under the skin, we humans are remarkably alike. The average genetic difference between two Icelandic villagers or between two Kenyans greatly exceeds the group difference between Icelanders and Kenyans (Cavalli-Sforza et al., 1994; Rosenberg et al., 2002). Moreover, looks can deceive. Light-skinned Europeans and dark-skinned Africans are genetically closer than are dark-skinned Africans and dark-skinned Aboriginal Australians.

Race is not a neatly defined biological category. Many social scientists see race primarily as a social construction without well-defined physical boundaries, as each race blends seamlessly into the race of its geographical neighbors (Helms et al., 2005; Smedley & Smedley, 2005). In one genetic analysis of more than 160,000 people living in the United States, most with less than 28 percent African ancestry said they were White; those with more than 28 percent mostly said they were African-American (Byrc et al., 2015). Moreover, with increasingly mixed ancestries, more and more people defy neat racial categorization and self-identify as multiracial (Pauker et al., 2009).

The intelligence test performance of today's better-fed, better-educated, and more test-prepared population exceeds that of the 1930s population—by a greater margin than the intelligence test score of the average White today exceeding that of the average Black (Flynn, 2012; Pietschnig & Voracek, 2015; Trahan et al., 2014). One research review noted that the average intelligence test performance of today's sub-Saharan Africans is the same as that of British adults in 1948 (Wicherts et al., 2010). No one credits genetics for such generation-to-generation differences.

When Blacks and Whites have or receive the same pertinent knowledge, they exhibit similar information-processing skill. "The data support the view that cultural differences in the provision of information may account for racial differences in [intelligence test performance]," reported researchers Joseph Fagan and Cynthia Holland (2007a).

Schools and culture matter. Countries whose economies create a large wealth gap between rich and poor tend also to have a large rich-versus-poor intelligence test score gap (Nisbett, 2009). In China and Turkey, people in poorer regions have the lowest intelligence test scores, and those in wealthier regions have the highest (Lynn et al., 2015, 2016). Moreover, educational policies such as kindergarten attendance, school discipline, and instructional time per year predict national differences in intelligence and knowledge tests (Lynn & Vanhanen, 2012; Rindermann & Ceci, 2009). Math achievement, aptitude test differences, and especially grades may reflect conscientiousness more than competence (Poropat, 2014). Asian students, who have outperformed North American students on such tests, have also spent 30 percent more time in school and much more time in and out of school studying math (Geary et al., 1996; Larson & Verma, 1999; Stevenson, 1992). Women in college and university similarly outperform equally able men, thanks partly to their greater conscientiousness (Keiser et al., 2016).

In different eras, different ethnic groups have experienced golden ages —periods of remarkable achievement. Twenty-five hundred years ago, it was the Greeks and the Egyptians, then the Romans. In the eighth and ninth centuries, genius seemed to reside in the Arab world. Five hundred years ago, the Aztec Indians and the peoples of Northern Europe were the superachievers. Today, many people notice Asian technological genius and Jewish cultural success. Cultures rise and fall over centuries; genes do not. That fact makes it difficult to attribute a natural superiority to any racial or ethnic group.

World Scrabble champs In 2015, Team Nigeria was the top country in the World Scrabble Championship. Five of its six members finished among the top

50 contestants, including Wellington Jighere, center, the individual world Scrabble champion.

Moreover, consider the striking results of studies that reveal a shrinking White/Black aptitude gap over time and with more equal education (Nisbett, 2009). One national study looked back over the mental test performances of White and Black young adults after graduation from college. From eighth grade through the early high school years, the average aptitude score of the White students increased, while that of the Black students decreased—creating a gap that reached its widest point at about the time that high school students like you take college admissions tests. But during college, the Black students' scores increased "more than four times as much" as those of their White counterparts, thus greatly decreasing the aptitude gap. "It is not surprising," concluded researcher Joel Myerson and his colleagues (1998), "that as Black and White students complete more grades in high school environments that differ in quality, the gap in cognitive test scores widens. At the college level, however, where Black and White students are exposed to educational environments of comparable quality . . . many Blacks are able to make remarkable gains, closing the gap in test scores."

The Question of Bias

64-3 Are intelligence tests inappropriately biased? How does stereotype threat affect test-takers’ performance?

If one assumes that *race* is a meaningful concept, the debate over racial differences in intelligence divides into three camps (Hunt & Carlson, 2007):

- There are genetically disposed racial differences in intelligence.
- There are socially influenced racial differences in intelligence.
- There are racial differences in test scores because the tests are inappropriate or biased.

We have considered group difference from the first and second perspectives. Let’s turn now to the third: Are intelligence tests biased? The answer depends on which of two very different definitions of bias we use.

Two Meanings of Bias

The *scientific* meaning of *bias* hinges on a test’s validity—on whether it predicts future behavior only for some groups of test-takers. For example, if the SAT accurately predicted the college achievement of women but not that of men, then the test would be biased. In this statistical meaning of the term, the near-consensus among psychologists (as summarized by the U.S. National Research Council’s Committee on Ability Testing and the American Psychological Association’s Task Force on Intelligence) has been that the major U.S. aptitude tests are *not* biased (Berry & Zhao, 2015; Neisser et al., 1996; Wigdor & Garner, 1982). The tests’ predictive validity is roughly the same for women and men, for various races, and for rich and poor. If an intelligence test score of 95 predicts slightly below-average grades, that rough prediction usually applies equally to all.

But we can also consider a test biased if it detects not only innate differences in intelligence but also performance differences caused by cultural experiences. This in fact happened to Eastern European immigrants in the early 1900s. Lacking the experience to answer questions about their new culture, many were classified as “feebleminded.” In this popular sense, intelligence tests are biased. They measure your developed abilities, which reflect, in part, your education and experiences.

You may have read examples of intelligence test items that make assumptions (for example, that a cup goes with a saucer). Such items bias the test (against those who do not use saucers). Could such questions explain cultural differences in test performance? In such cases, tests can be a vehicle for discrimination, consigning potentially capable children (some of whom may have a different native language) to unchallenging classes and dead-end jobs. Thus, some intelligence researchers recommend creating culture-neutral questions—such as assessing people’s ability to learn novel words, sayings, and analogies—to enable *culture-fair* aptitude tests (Fagan & Holland, 2007b, 2009).

Defenders of the existing aptitude tests have noted that racial group differences persist on nonverbal items, such as counting digits backward (Jensen, 1983, 1998). Moreover, they add, blaming the test for a group’s lower scores is like blaming a messenger for bad news. Why blame the tests for exposing unequal experiences and opportunities? If, because of malnutrition, people were to suffer stunted growth, would you blame the measuring stick that reveals it? If unequal past experiences predict unequal future achievements, a valid aptitude test will detect such inequalities.

So, test-makers’ expectations can introduce bias in an intelligence test. This is consistent with an observation we have seen throughout this text: Our expectations and attitudes can influence our perceptions and behaviors. This is also true for the person taking the test.

Test-Takers’ Expectations

When Steven Spencer and his colleagues (1997) gave a difficult math test to equally capable men and women, women did not do as well—except when they had been led to expect that women usually do as well as men on the test. Expecting to struggle with the math affected their performance. There was a “threat in the air” (Spencer et al., 2016). And with Claude

Steele and Joshua Aronson, Spencer (2002) again observed this self-fulfilling **stereotype threat** when Black students performed worse after being reminded of their race just before taking verbal aptitude tests. Follow-up experiments have confirmed that negatively stereotyped minorities and women may have unrealized academic and professional potential (Grand, 2016; Nguyen & Ryan, 2008; Walton & Spencer, 2009). If, when taking an intelligence test or performing a work-related task, you are worried that your group or "type" often doesn't do well, your self-doubts and self-monitoring may hijack your working memory and impair your performance (Hutchison et al., 2013). Such thoughts, and worries about what others are thinking about you, can be distracting. For such reasons, stereotype threat may impair attention, performance, and learning (Inzlicht & Kang, 2010; Rydell et al., 2010). Remove the threat—by labeling the assessment as a "warm-up" exercise rather than a "test"—and stereotyped minorities often perform better (Taylor & Walton, 2011).

stereotype threat

a self-confirming concern that one will be evaluated based on a negative stereotype.

Stereotype threat helps explain why Blacks have scored higher when tested by Blacks than when tested by Whites (Danso & Esses, 2001; Inzlicht & Ben-Zeev, 2000). It implies a possible effect of non-Black teachers having lower expectations for Black students than do Black teachers (Gershenson et al., 2016). And it gives us insight into why women have scored higher on math tests with no male test-takers present, and why women's online chess performance drops sharply when they *think* they are playing a male opponent (Maass et al., 2008).

> “ *Math class is tough!* ”
>
> *"Teen Talk" talking Barbie doll (introduced July 1992, recalled October 1992)*

Steele (1995, 2010) concludes that telling students they probably won’t succeed (as is sometimes implied by remedial “minority support” programs) functions as a stereotype that can erode performance. Over time, such students may detach their self-esteem from academics and look for recognition elsewhere. Indeed, as African-American male students progress from eighth to twelfth grade, a growing disconnect appears between their grades and their self-esteem, and they tend to underachieve (Osborne, 1997).

One experiment randomly assigned some African-American seventh graders to write for 15 minutes about their most important values (Cohen et al., 2006, 2009). That simple exercise in self-affirmation boosted their semester grades in two replications. Can a brief confidence-boosting exercise actually increase school achievement? “It was hard for us to believe,” reported Geoffrey Cohen (2013), “but we’ve replicated it [again] since,” including among women in college physics. Other research teams also have reproduced the benefits of the self-affirmation exercise (Bowen et al., 2013; Cohen & Sherman, 2014; Harackiewicz et al., 2014, 2016). When challenged to believe in their potential, increase their sense of belonging, or focus on intelligence as malleable (rather than fixed), disadvantaged university students have likewise earned markedly higher grades and have had lower dropout rates (Tibbetts et al., 2016; Yeager et al., 2016b).

> “*Almost all the joyful things of life are outside the measure of IQ tests.*”
>
> *Madeleine L’Engle, A Circle of Quiet, 1972*

* * *

What, then, can we realistically conclude about aptitude tests and bias? The tests are not biased in the scientific sense of failing to make valid statistical predictions for different groups. But they are indeed biased in one sense—sensitivity to performance differences caused by cultural experience. Are the tests discriminatory? Again, the answer can be *Yes* or *No*. In one sense, *Yes*, their purpose is to discriminate—to distinguish among individuals. In another sense, *No,* their purpose is to reduce discrimination by decreasing reliance on subjective criteria for school and job placement—who you know, what school you're from, or whether you are the "right kind of person." Civil service aptitude tests, for example, were devised to discriminate more fairly and objectively by reducing the political, racial, ethnic, and gender discrimination that preceded their use. Banning aptitude tests would lead those who decide on jobs and admissions to rely more on other considerations, such as personal opinion.

> “*[Einstein] showed that genius equals brains plus tenacity squared.*”
>
> *Walter Isaacson, "Einstein's Final Quest," 2009*

Perhaps, then, our goals for tests of mental abilities should be threefold. First, we should realize the benefits that intelligence testing pioneer Alfred Binet foresaw—to enable schools to recognize who might profit most from early intervention. Second, we must remain alert to Binet's fear that intelligence test scores may be misinterpreted as literal measures of a person's worth and potential. Third, we must remember that the competence that general intelligence tests sample is important; it helps enable success in some life paths. But it reflects only one aspect of personal competence (Stanovich et al., 2013; Stanovich & West, 2014a,b). Our rationality, practical intelligence, and emotional intelligence matter, too, as do other forms of creativity, talent, and character.

The point to remember: There are many ways of being successful; our differences are variations of human adaptability. Life's great achievements result not only from "can do" abilities (and fair opportunity) but also from "will do" motivation. Competence + Diligence → Accomplishment.

✓ Check Your Understanding

Ask Yourself

- How have your expectations influenced your own test performance? What steps could you take to control this influence?

Test Yourself

- What psychological principle helps explain why women tend to perform more poorly when they believe their online chess opponent is male?
- What is the difference between a test that is biased culturally, and a test that is biased in terms of its validity?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 64 REVIEW

64-1 How and why do the genders differ in mental ability scores?

- Males and females tend to have the same average intelligence test scores. They differ in some specific abilities.
- Girls are better spellers, more verbally fluent, better at locating objects, better at detecting emotions, and more sensitive to touch, taste, and color.
- Boys outperform girls at spatial ability and related mathematics, though boys and girls hardly differ in math computation. Boys also outnumber girls at the low and high extremes of mental abilities.
- Psychologists debate evolutionary, brain-based, and cultural explanations of such gender differences.

64-2 How and why do racial and ethnic groups differ in mental ability scores?

- Racial and ethnic groups differ in their average intelligence test scores.
- The evidence suggests that environmental differences are largely, perhaps entirely, responsible for these group differences.

64-3 Are intelligence tests inappropriately biased? How does stereotype threat affect test-takers' performance?

- Aptitude tests aim to predict how well a test-taker will perform in a given situation. So they are necessarily "biased" in the sense that they are sensitive to performance differences caused by cultural experience.
- By "inappropriately biased," psychologists mean that a test predicts less accurately for one group than for another. In this sense, most experts consider the major aptitude tests unbiased.
- *Stereotype threat*, a self-confirming concern that one will be evaluated

based on a negative stereotype, affects performance on all kinds of tests.

Multiple-Choice Questions

1. Which of the following is true of boys compared with girls?

a. Boys have a higher average intelligence score.
b. Boys are better spellers than girls.
c. Boys are better at detecting emotions.
d. Boys are more verbally fluent.
e. Boys are more likely to be represented among those scoring extremely low as well as those scoring extremely high on tests of mental abilities.

2. Which of the following provides the best evidence that race is more of a social construct than a biological category?

a. People of varying ancestry may categorize themselves as having the same race.
b. Scores on tests of mental abilities vary by race.
c. Behavior traits are associated with race.
d. Skin cancer rates vary by race.
e. The incidence of high blood pressure varies by race.

3. According to most experts, intelligence tests are not biased because

a. the average scores for various racial and ethnic groups do not differ by much.
b. the tests do a pretty good job of predicting what they are supposed to predict.
c. cultural background has little influence on test scores.
d. scores on the test are not very stable even when you don’t consider race.
e. scores are increasing for almost all groups because of the Flynn effect.

Practice FRQs

1. Luis is a Mexican-American high school student with a 3.8 GPA. He recently completed his SAT in a room with a White proctor and an all White group of students. His score was much lower than he predicted based on the practice exam he took during his English class at his largely Hispanic high school. Explain how each of the following may have contributed to his lower score:
    - Bias
    - Stereotype threat

Answer

1 point: Racial group differences do exist on some types of intelligence tests. If the questions on Luis' test were reflective of a type of vocabulary that Luis had not been exposed to, even if unintentional, then the test that he took was biased against him. Page 657

1 point: The stereotype threat would be something that Luis would impose on himself. If he had heard that Hispanic students generally do more poorly on the SAT than do White students, he may have looked around the room and felt pressure internally and not have done as well as he was capable of doing. Page 657

2. Explain three reasons why racial differences in intelligence might be caused by environmental factors.

AP® EXAM PRACTICE QUESTIONS

Multiple-Choice Questions

1. People are said to have an intellectual disability if they have difficulty adapting to the demands of independent living and have IQ scores below

a. 60.
b. 70.
c. 80.
d. 90.
e. 100.

2. Charles Spearman’s *g* refers to

a. general intelligence.
b. grouped intelligence factors.
c. genetic intelligence.
d. generated creativity.

e. generalized reliability.

3. Which of the following individuals would best represent our understanding of fluid versus crystallized intelligence?

a. James is 80 and has just solved a math equation that has been puzzling him for the last 40 years.
b. Luis is 22 and has written several successful novels.
c. Alice is 25 and has discovered a new chemical element.
d. As a high school student, Alex changed the way people thought about a local homeless man by doing research into his life.
e. After watching the sky for 50 years Nate finally discovered a new planet.

4. What would be true of a thermometer that always reads three degrees lower than the actual temperature?

a. It is valid but not reliable.
b. It is both reliable and valid.
c. It is neither reliable nor valid.
d. It is not valid, but you cannot determine if it is reliable from the information given.
e. It is reliable but not valid.

5. What is the benefit of standardizing an intelligence test?

a. To counter rising intelligence test scores
b. To measure the extent to which the test actually predicts what it promises
c. To provide a basis for comparing scores against a pretested group
d. To determine if the test yields dependably consistent results
e. To calculate the relative effects of nature and nurture on intelligence

6. Achievement tests are to aptitude tests as

a. verbal performance is to spatial performance.
b. elementary school skills are to secondary school skills.
c. measurement is to prediction.

d. reliability is to validity.
e. general intelligence is to multiple intelligences.

7. Howard Gardner found evidence of multiple intelligences in individuals who scored low on intelligence but had an area of exceptional ability—for example, to make complex calculations. These people have

a. the Flynn effect.
b. savant syndrome.
c. advanced mental age.
d. Wechsler syndrome.
e. intelligence heritability.

8. Which of the following is one of Robert Sternberg’s types of intelligence?

a. Naturalistic intelligence
b. General intelligence
c. Practical intelligence
d. Savant intelligence
e. Kinesthetic intelligence

9. Researchers studying the effects of genes on intelligence have found that

a. intelligence is affected by many genes working together.
b. there is a gene that is involved in the intelligence of men but not women.
c. there is a gene that is involved in the intelligence of women but not men.
d. a single gene is involved in the intelligence of both men and women.
e. there is no evidence that genes play a role in intelligence.

0. The Flynn effect refers to the

a. superiority of certain racial and ethnic groups on intelligence tests.
b. extreme scores (very high and very low scores) that are more

common for males than for females on math tests.
c. stereotype threat that might cause some Black students to underperform on standardized tests.
d. predictive ability of intelligence tests.
e. gradual increase in average intelligence score of the general population over the last several decades.

1. If Lanie is able to tell when her husband is upset by noticing subtle changes in his facial expressions, she might be said to have a high degree of

a. emotional intelligence.
b. naturalistic intelligence.
c. practical intelligence.
d. spatial intelligence.
e. adaptive intelligence.

2. Heritability of intelligence refers to

a. the extent to which a person’s intelligence is caused by genetics.
b. the effect of adoption on the intelligence of adopted children.
c. the amount of group variation in intelligence that can be attributed to genetics.
d. the extent to which the quality of schools and other environmental factors determine intelligence.
e. the correlation between intelligence test scores of identical twins.

3. The most widely used modern intelligence test was developed by

a. Alfred Binet.
b. Louis Terman.
c. Robert Sternberg.
d. David Wechsler.
e. Howard Gardner.

4. Students who do well on college entrance exams generally do well in their first year of college. This helps establish that these exams have

a. predictive validity.
b. split-half reliability.
c. content validity.
d. test-retest reliability.
e. standard validity.

5. The purpose of Alfred Binet's early intelligence test was to

a. predict how children would do in school.
b. identify differences among ethnic and racial groups.
c. help French graduates find the occupation in which they were most likely to succeed.
d. establish the scientific definition of intelligence.
e. facilitate "genetic breeding" experiments.

6. The original formula for a child's intelligence quotient compared a child's

a. aptitude to his or her school performance.
b. mental age to his or her chronological age.
c. intelligence to his or her siblings' intelligence.
d. intelligence to his or her parents' intelligence.
e. math intelligence to his or her verbal intelligence.

7. If the scores on an intelligence test form a normal curve with a standard deviation of 15,

a. the mean, median, and mode are 100.
b. 68 percent of scores are between 85 and 115.
c. 60 percent of test-takers earned at least a 100.
d. a and b only are true.
e. a, b, and c are true.

8. If approached on the street by a stranger and asked to make a guess about their IQ score, your best guess would be

a. 50.
b. 75.

c. 100.
d. 125.
e. 150.

Free-Response Questions

1. Shervin is a high school student who excels in academics and usually scores very high on academic standardized tests. His friend, Hany, struggles in his coursework and with standardized tests, but is a brilliant pianist and dancer.

For each of the following psychologists, briefly explain his theory and identify how that psychologist might describe Shervin's and Hany's intelligence.

- Howard Gardner
- Robert Sternberg
- Charles Spearman

Rubric for Free Response Question 1

1 point: Gardner believes there are eight relatively independent intelligences: linguistic, musical, logical-mathematical, spatial, bodily-kinesthetic, intrapersonal, interpersonal, and naturalist. Gardner has also proposed a possible ninth, existential intelligence. Page 627

1 point: Gardner might describe Shervin as having high logical-mathematical and linguistic intelligence, and Hany as having high musical and bodily-kinesthetic intelligence. Page 627

1 point: Sternberg's triarchic theory proposes three intelligences: creative, analytical, and practical. Page 628

1 point: Sternberg might predict that Shervin would score high in analytical intelligence and Hany would score high in creative intelligence. Page 628

1 point: According to Spearman's general intelligence theory, each individual has a general, underlying mental ability that is represented in all intelligent behavior. For example, if an individual is above average in verbal intelligence, then she will most likely be at least average, if not above average in spatial or reasoning ability as well. Page 626

1 point: Spearman might have predicted that Shervin would have a high general intelligence, and Hany would not, because Spearman would not have included creativity in music and dance in tests of general intelligence. Page 626

2. The principal of a new elementary school wants to give an IQ test to all students when they enter the school. The students will then be placed in groups of students with similar IQ scores. The principal assures the community that this plan is supported by scientific research and will improve education for all students, regardless of their ability.

- Using evidence, present an argument for or against intelligence testing for children early in life.
- Using evidence, present an argument for or against schools that "track" children based on intelligence test scores, separating high scorers from those with lower scores.
- Using evidence, present an argument supporting the claim that environmental influences affect intelligence.
- Using evidence, present an argument supporting the claim that labeling or tracking students could lead to stereotype threat.

(4 points)

3. Professor Emic wants to first develop an intelligence test that can be used cross-culturally, and then to assess the reliability and validity of that test.

Briefly explain how Professor Emic could examine the following characteristics about this new intelligence test:

- Standardization
- Reliability
- Validity
- Bias

69 Other Disorders

I felt the need to clean my room at home in Indianapolis every

> Sunday and would spend four to five hours at it. I would take every book out of the bookcase, dust and put it back. At the time I loved doing it. Then I didn't want to do it anymore, but I couldn't stop. The clothes in my closet hung exactly two fingers apart. . . . I made a ritual of touching the wall in my bedroom before I went out because something bad would happen if I didn't do it the right way. I had a constant anxiety about it as a kid, and it made me think for the first time that I might be nuts.
>
> *Marc, diagnosed with obsessive-compulsive disorder (from Summers, 1996)*

> Whenever I get depressed it's because I've lost a sense of self. I can't find reasons to like myself. I think I'm ugly. I think no one likes me. . . . I become grumpy and short-tempered. Nobody wants to be around me. I'm left alone. Being alone confirms that I am ugly and not worth being with. I think I'm responsible for everything that goes wrong.
>
> *Greta, diagnosed with depression (from Thorne, 1993, p. 21)*

> Voices, like the roar of a crowd, came. I felt like Jesus; I was being crucified. It was dark. I just continued to huddle under the blanket, feeling weak, laid bare and defenseless in a cruel world I could no longer understand.
>
> *Stuart, diagnosed with schizophrenia (from Emmons et al., 1997)*

Now and then, all of us feel, think, or act in ways that may resemble a psychological disorder. We feel anxious, depressed, withdrawn, or suspicious. So it's no wonder that we are drawn to try to understand disturbed psychological states—we sometimes see ourselves in the mental illnesses we study. "To study the abnormal is the best way of understanding the normal," said William James *(1842–1910)*.

Personally or through friends or family, we may experience the bewilderment and pain of unexplained physical symptoms, irrational fears, or a feeling that life is not worth living. Among American college students, 1 in 3 report an apparent mental health problem (Eisenberg et al., 2011).

Worldwide, more than half a billion people live with mental or behavior disorders (WHO, 2017a). Although their rates and symptoms vary by culture, no known society is free of two terrible disorders—major depressive disorder and schizophrenia (Baumeister & Härter, 2007; Draguns, 1990a,b, 1997). This unit examines these and other disorders. Unit XIII considers their *treatment.*

Module **65 Introduction to Psychological Disorders**

LEARNING TARGETS

- **65-1 Explain how we draw the line between normality and disorder.**
- **65-2 Contrast how the medical model and the biopsychosocial approach influence our understanding of psychological disorders.**
- **65-3 Describe how and why clinicians classify psychological disorders, and explain why some psychologists criticize the use of diagnostic labels.**
- **65-4 Discuss the controversy over attention-deficit/hyperactivity disorder.**
- **65-5 Examine whether psychological disorders predict violent behavior.**
- **65-6 Describe how many people have, or have had, a psychological disorder, and explore whether poverty is a potential risk factor.**

Introduction to Psychological Disorders

Most people would agree that someone who is depressed and stays mostly in bed for three months has a psychological disorder. But what about a grieving father who can’t resume his usual social activities three months after his child has died? Where should we draw the line between sadness and depression? Between a fear and a phobia? Between normality and abnormality? Let’s start with these questions:

- How should we *define* psychological disorders?
- How should we *understand* disorders? How do underlying biological factors contribute to disorder? How do troubling environments influence our well-being? And how do these effects of nature and nurture interact?
- How should we *classify* psychological disorders? And can we do so in a way that allows us to help people without stigmatizing or labeling them?
- What do we know about *rates* of psychological disorders? How many people have them? Who is vulnerable, and when?

Defining Psychological Disorders

65-1 How do we draw the line between normality and disorder?

A **psychological disorder** is a syndrome (collection of symptoms) marked by a "clinically significant disturbance in an individual's cognition, emotion regulation, or behavior" (American Psychiatric Association, 2013). Such thoughts, emotions, or behaviors are *dysfunctional* or *maladaptive*—they interfere with normal day-to-day life. Believing your home must be thoroughly cleaned every weekend is not a disorder. But if cleaning rituals interfere with work and leisure, as Marc's uncontrollable rituals did, they may be signs of a disorder. Occasional sad moods that persist and become disabling may likewise signal a psychological disorder.

psychological disorder

a syndrome marked by a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior.

Distress often accompanies such dysfunction. Marc, Greta, and Stuart were all distressed by their thoughts, emotions, or behaviors.

I'm
Falling 4
U.
PROM?

Left: Carol Beckwith; Right: Francois Dubourdeau/Skydive East Tennessee

Culture and normality Young men of the West African Wodaabe tribe traditionally put on decorative makeup and costumes to attract women. Young American men may plan elaborate invitations for big events, as did this student (right) who appealed (successfully) to his date for prom. Each culture may view the other's behavior as abnormal.

Over time, definitions of what makes for a “significant disturbance” have varied. From 1952 through December 9, 1973, homosexuality was classified as a psychological disorder. By day’s end on December 10, it was not. The American Psychiatric Association made this change because more and more of its members no longer viewed same-sex attraction as a psychological problem. Such is the power of shifting societal beliefs. (Later research revealed, however, that the *stigma and stresses* that people who are gay, lesbian, transgender, and gender nonconforming often experience can increase the risk of mental health problems [Hatzenbuehler et al., 2009; Meyer, 2003].) In the twenty-first century, other controversies swirl over new or altered diagnoses in the most recent classification tool for describing disorders.

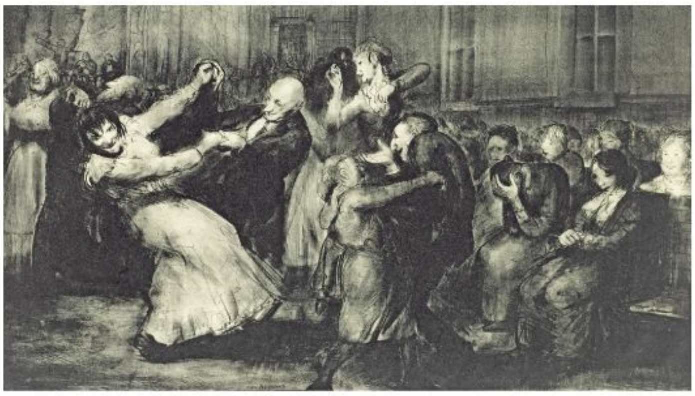
> “*Who in the rainbow can draw the line where the violet tint ends and the orange tint begins? Distinctly we see the difference of the colors, but where exactly does the one first blendingly enter into the other? So with sanity and insanity.*”
>
> *Herman Melville*, Billy Budd, Sailor, *1924*

Understanding Psychological Disorders

65-2 How do the medical model and the biopsychosocial approach influence our understanding of psychological disorders?

The way we view a problem influences how we try to solve it. In earlier times, people often viewed strange behaviors as evidence of strange forces—the movements of the stars, godlike powers, or evil spirits—at work. Had you lived during the Middle Ages, you might have said "The devil made him do it." Believing that, you might have approved of a harsh cure that would drive out the evil demon. Thus, people considered "mad" were sometimes caged or given "therapies" such as genital mutilation, beatings, removal of teeth or lengths of intestines, or transfusions of animal blood (Farina, 1982).

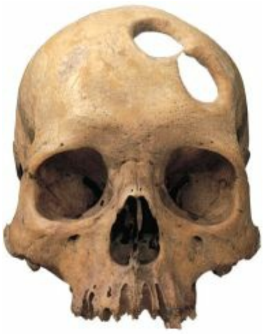
Reformers such as Philippe Pinel (1745–1826) in France opposed such brutal treatments. Madness is not demonic possession, he insisted, but a sickness of the mind caused by severe stress and inhumane conditions. Curing the illness, he said, requires *moral treatment*, including boosting patients' spirits by unchaining them and talking with them. He and others worked to replace brutality with gentleness, isolation with activity, and filth with clean air and sunshine.



Dance in a Madhouse, 1917 (litho)/Bellows, George Wesley (1882–1925) /SAN DIEGO MUSEUM OF ART/San Diego Museum of Art, USA/Bridgeman Images

"Moral treatment" Under Philippe Pinel's influence, hospitals sometimes sponsored patient dances, often called "lunatic balls," as depicted in this painting by George Bellows (Dance in a Madhouse).

In some places, cruel treatments for mental illness—including chaining people to beds or confining them in spaces with wild animals—linger even today. The World Health Organization has launched a reform that aims to transform hospitals worldwide “into patient-friendly and humane places with minimum restraints” (WHO, 2014a).



John W. Verano

Yesterday’s “therapy” Through the ages, psychologically disordered people have received brutal treatments, including the trephination evident in this Stone Age patient’s skull. Drilling skull holes like these may have been an attempt to release evil spirits and cure those with mental disorders. Did this patient survive the “cure”?

The Medical Model

By the 1800s, a medical breakthrough prompted further reforms. Researchers discovered that syphilis infects the brain and distorts the mind. This discovery triggered an eager search for physical causes of other mental disorders and for treatments that would cure them. Hospitals replaced asylums, and the **medical model** of mental disorders was born. This model is reflected in the terms we still use today. We speak of the mental *health* movement: A mental *illness* (also called a psycho*pathology*) needs to be *diagnosed* on the basis of its *symptoms*. It needs to be *treated* through *therapy*, which may include time in a psychiatric *hospital*.

medical model

the concept that diseases, in this case psychological disorders, have physical causes that can be *diagnosed, treated*, and, in most cases, *cured*, often through treatment in a *hospital*.

The medical perspective has been energized by more recent discoveries that genetically influenced abnormalities in brain structure and biochemistry contribute to many disorders (Insel & Cuthbert, 2015). A growing number of clinical psychologists now work in medical hospitals, where they collaborate with physicians to determine how the mind and body operate together.

FYI

Mental disorders due to a medical condition have also been called *organic disorders*.

The Biopsychosocial Approach

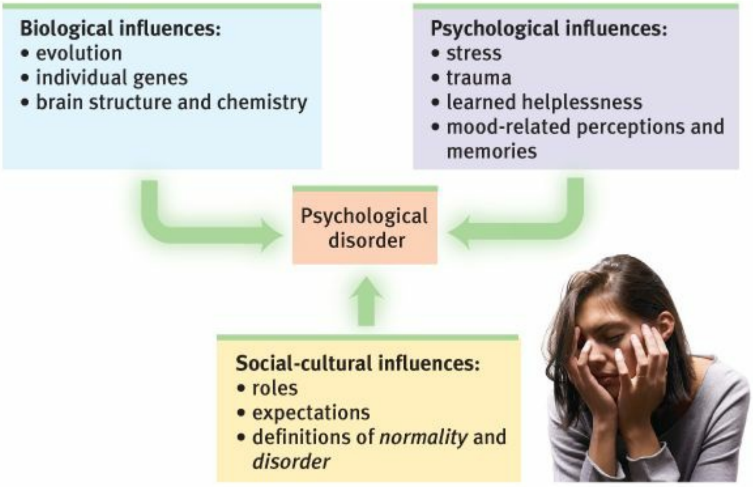
To call psychological disorders "sicknesses" tilts research heavily toward the influence of biology and away from the influence of our personal histories and social and cultural surroundings. But in the study of disorders, as in so many other areas, biological, psychological, and social-cultural influences together weave the fabric of our behaviors, our thoughts, and our feelings. As individuals, we differ in the amount of stress we experience and in the ways we cope with stressors. Cultures also differ in their sources of stress and in their traditional ways of coping. We are physically embodied and socially embedded.

Two disorders—major depressive disorder and schizophrenia—occur worldwide. From Asia to Africa and across the Americas, schizophrenia's symptoms often include irrationality and incoherent speech. Other disorders tend to be associated with specific cultures. Latin America lays claim to *susto*, a condition marked by severe anxiety, restlessness, and a fear of black magic. In Japanese culture, people may experience *taijin-kyofusho*—social anxiety about their appearance, combined with a readiness to blush and a fear of eye contact. The eating disorders anorexia nervosa and bulimia nervosa occur mostly in food-abundant Western cultures. Such disorders may share an underlying dynamic (such as anxiety) while differing in the symptoms (an eating problem or a type of fear) manifested in a particular culture. Even disordered aggression may have varying explanations in different cultures. In Malaysia, *amok* describes a sudden outburst of violent behavior (as in the English phrase “run amok”).

FYI

Increasingly, North American disorders, such as eating disorders, have spread across the globe (Watters, 2010).

Disorders reflect genetic predispositions and physiological states, inner psychological dynamics, and social and cultural circumstances. The biopsychosocial approach emphasizes that mind and body are inseparable (**Figure 65.1**). Negative emotions can contribute to physical illness, and physical abnormalities can likewise contribute to negative emotions. The biopsychosocial approach gave rise to the *stress vulnerability model (*also called the *diathesis-stress model*). This model suggests that individual characteristics combine with environmental stressors to increase or decrease the likelihood of developing a psychological disorder (Monroe & Simons, 1991; Zuckerman, 1999). Research on **epigenetics** (literally, “in addition to genetic”) supports the vulnerability-stress model by showing how our DNA and our environment interact. In one environment, a gene will be *expressed*, but in another, it may lie dormant. For some, that will be the difference between developing a disorder or not developing it.



Biological influences:
• evolution
• individual genes
• brain structure and chemistry
Psychological influences:
• stress
• trauma
• learned helplessness
• mood-related perceptions and memories
Psychological disorder
Social-cultural influences:
• roles
• expectations
• definitions of *normality* and *disorder*

Figure 65.1 The biopsychosocial approach to psychological disorders

Today's psychology studies how biological, psychological, and social-cultural factors interact to produce specific psychological disorders.

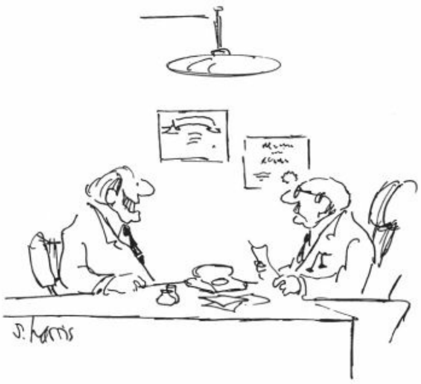
epigenetics

the study of environmental influences on gene expression that occur without a DNA change.

Classifying Disorders—and Labeling People

65-3 How and why do clinicians classify psychological disorders, and why do some psychologists criticize the use of diagnostic labels?

In biology, classification creates order. To classify an animal as a "mammal" says a great deal—that it is warm-blooded, has hair or fur, and produces milk to nourish its young. In psychiatry and psychology, too, classification orders and describes symptoms. To classify a person's disorder as "schizophrenia" suggests that the person talks incoherently, has bizarre beliefs, shows either little emotion or inappropriate emotion, or is socially withdrawn. "Schizophrenia" is a quick way to describe a complex disorder.



Sidney Harris

"I'm always like this, and my family was wondering if you could prescribe a mild depressant."

But diagnostic classification gives more than a thumbnail sketch of a person's disordered behavior, thoughts, or feelings. In psychiatry and psychology, classification also aims to *predict* a disorder's future course, *suggest* appropriate treatment, and *prompt research* into its causes. To study a disorder, we must first name and describe it.

In the United States, the most common tool for describing disorders and estimating how often they occur is the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders,* now in its fifth edition (**DSM-5**).[1] Physicians and mental health workers use the detailed “diagnostic criteria and codes” in the DSM-5 to guide medical diagnoses and treatment. For example, a person may be diagnosed with and treated for insomnia disorder if he or she meets all of the criteria in **Table 65.1**. The DSM-5’s diagnostic criteria and codes closely resemble those in the World Health Organization’s *International Classification of Diseases* (ICD), making it easy to track worldwide trends in psychological disorders.

DSM-5
the American Psychiatric Association’s *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition; a widely used system for classifying psychological disorders.

TABLE 65.1 Insomnia Disorder

• Feeling unsatisfied with amount or quality of sleep (trouble falling asleep, staying asleep, or returning to sleep)
• Sleep disruption causes distress or diminished everyday functioning
• Happens three or more nights each week
• Occurs during at least three consecutive months
• Happens even with sufficient sleep opportunities
• Independent from other sleep disorders (such as narcolepsy)
• Independent from substance use or abuse
• Independent from other mental disorders or medical conditions

Source: American Psychiatric Association, 2013.

In the new DSM-5, some diagnostic labels have changed. The conditions formerly called “autism” and “Asperger’s syndrome” were combined under the label *autism spectrum disorder*. “Mental retardation” became *intellectual disability*. New disorders, such as *hoarding disorder* and *binge-eating disorder*, were added.

Some of the new or altered diagnoses are controversial. *Disruptive mood dysregulation disorder* is a new DSM-5 diagnosis for children "who exhibit persistent irritability and frequent episodes of behavior outbursts three or more times a week for more than a year." Will this diagnosis assist parents who struggle with unstable children, or will it "turn temper tantrums into a mental disorder" and lead to overmedication, as the chair of the previous DSM edition warned (Frances, 2012)?

In real-world tests (*field trials)* assessing the reliability of the new DSM-5 categories, some diagnoses have fared well and others have fared poorly (Freedman et al., 2013). Clinician agreement on *adult posttraumatic stress disorder* and *childhood autism spectrum disorder,* for example, was near 70 percent. (If one psychiatrist or psychologist diagnosed someone with one of these disorders, there was a 70 percent chance that another mental health worker would independently give the same diagnosis.) But for *antisocial personality disorder* and *generalized anxiety disorder,* agreement was closer to 20 percent.

Critics have long faulted the DSM for casting too wide a net and bringing "almost any kind of behavior within the compass of psychiatry" (Eysenck et al., 1983). Some now worry that the DSM-5's even wider net will extend the pathologizing of everyday life. For example, the DSM has broadened the diagnostic criteria for **attention-deficit/hyperactivity disorder (ADHD)**. For those who experience these challenging symptoms, diagnosis and treatment can be a relief and bring improved functioning (Kupfer, 2012; Maciejewski et al., 2016). However, critics suggest that the criteria are now too broad and may turn normal, childish rambunctiousness into a disorder (Frances, 2013, 2014). (See Thinking Critically About: ADHD—Normal High Energy or Disordered Behavior?) The DSM also now classifies severe grief following the death of a loved one as a possible *depressive disorder*. Critics suggest that such grief could instead simply be considered a "normal" reaction to tragic life events.

attention-deficit/hyperactivity disorder (ADHD)

a psychological disorder marked by extreme inattention and/or hyperactivity and impulsivity.

Seeking a new but complementary approach to classification, the U.S. National Institute of Mental Health has established the Research Domain Criteria (RDoC) project (Insel et al., 2010; NIMH, 2017). The RDoC aims to bring “the power of modern research approaches in genetics, neuroscience, and behavioral science” to the study of psychological disorders (Insel & Lieberman, 2013). This framework helps organize disorders according to behaviors and brain activity related to negative or positive emotions, cognition, social relationships, and arousal and sleep. Exploring these dimensions improves psychologists’ ability to classify and treat disorders.

Other critics of classification register a more basic complaint—that diagnostic labels can be subjective, or even value judgments masquerading as science. Once we label a person, we view that person differently (Bathje & Pryor, 2011; Farina, 1982; Sadler et al., 2012). Labels can change reality by putting us on alert for evidence that confirms our view. If we hear that a new co-worker is a nasty person, we may treat her suspiciously, leading her to respond as a mean-spirited person would. Teachers who were told certain students were “gifted” then acted in ways that elicited the behaviors they expected (Snyder, 1984). Labels can be self-fulfilling.

The biasing power of labels was clear in a classic and controversial study. David Rosenhan (1973) and seven others went to hospital admissions offices, complaining (falsely) of “hearing voices” saying *empty, hollow,* and *thud.* Apart from this complaint and giving false names and occupations, they answered questions truthfully. All eight healthy people were misdiagnosed with disorders.

Should we be surprised? Surely not. As one psychiatrist noted, if someone swallows blood, goes to an emergency room, and spits it up, we wouldn’t fault the doctor for diagnosing a bleeding ulcer. But what followed the diagnoses was startling. Until being released an average of 19 days later, those eight “patients” showed no other symptoms. Yet after analyzing their (quite normal) life histories, clinicians were able to "discover" the causes of their disorders, such as having mixed emotions about a parent. Even routine note-taking behavior was misinterpreted as a symptom.

DEMOCRAT
Martin J.
WALSH
FOR MAYOR
www.MartyWalsh.org

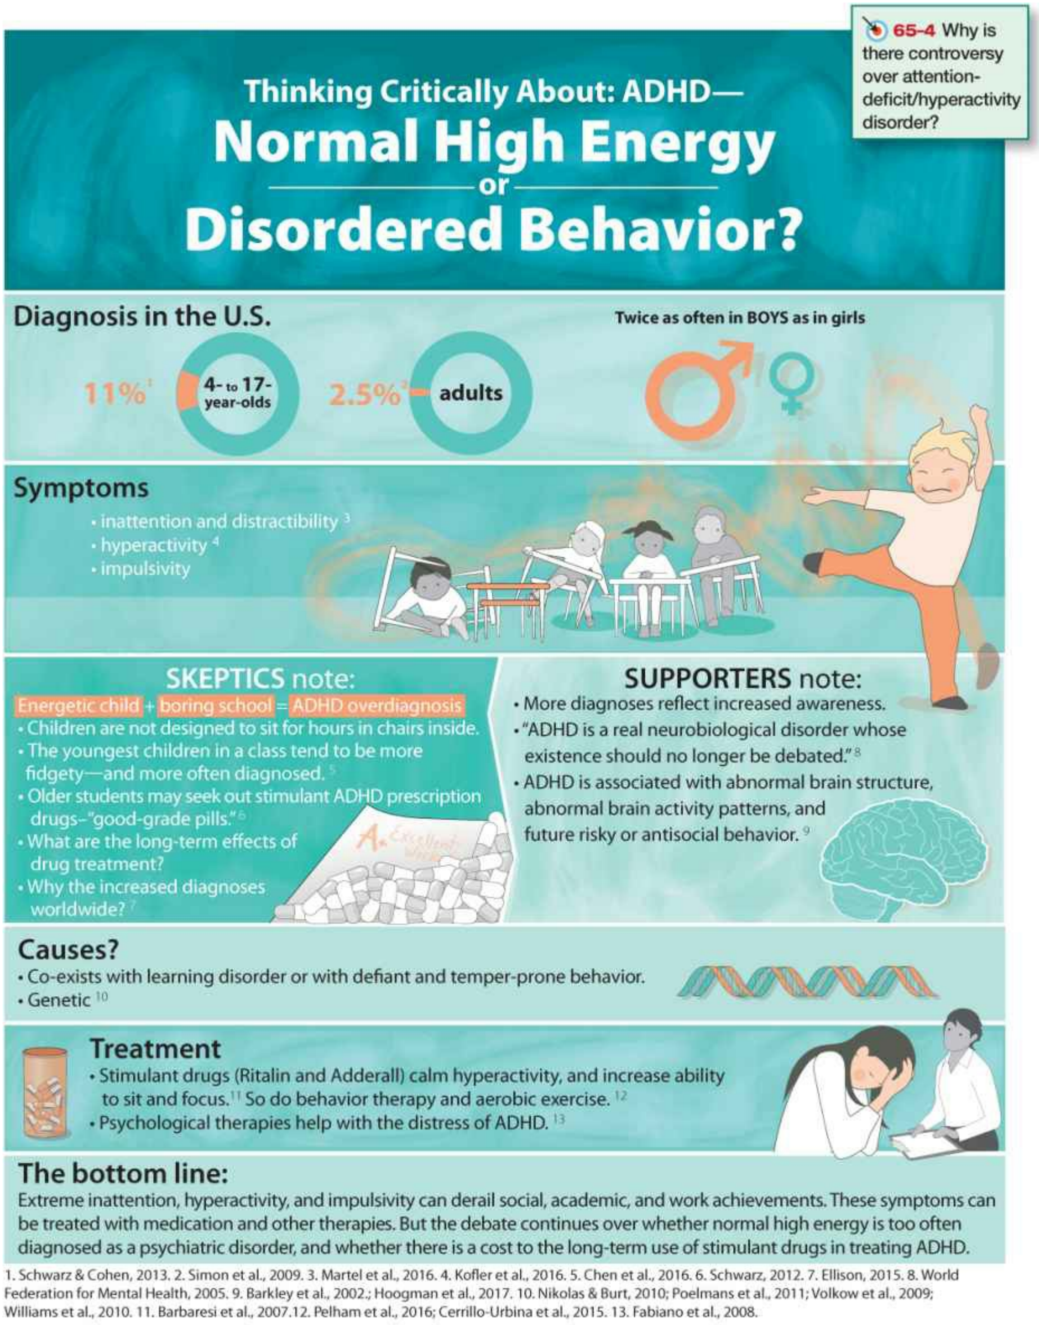
GRETCHEN ERTL/The New York Times/Redux Pictures

Struggles and recovery During his campaign, Boston Mayor Martin Walsh spoke openly about his past struggles with alcohol. His story of recovery helped him win in 2014—the closest Boston mayoral election in decades.

Labels matter. In another study, people watched recorded interviews. If told the interviewees were job applicants, the viewers perceived them as normal (Langer & Abelson, 1974; Langer & Imber, 1980). Other viewers who were told they were watching cancer or psychiatric patients perceived the same interviewees as "different from most people." Therapists who thought they were watching an interview of a psychiatric patient perceived him as "frightened of his own aggressive impulses," a "passive, dependent type," and so forth. A label can, as Rosenhan discovered, have "a life and an influence of its own."

Labels also have power in everyday life. Getting a job or finding a place to rent can be a challenge for people recently released from a psychiatric hospital. Label someone as "mentally ill" and people may fear them as potentially violent. That reaction may fade as people better understand that many psychological disorders involve diseases of the brain, not failures of character. Public figures have helped foster this understanding by speaking openly about their own struggles with disorders such as depression and substance abuse. The more contact we have with people with disorders, the more accepting our attitudes become (Corrigan et al., 2014).

65-4 Why is there controversy over attention-deficit/hyperactivity disorder?



Thinking Critically About: ADHD—

Normal High Energy or Disordered Behavior?

Diagnosis in the U.S.

11%[1] 4- to 17-year-olds

2.5%[2] adults

Twice as often in BOYS as in girls

Symptoms

- inattention and distractibility [3]
- hyperactivity [4]
- impulsivity

SKEPTICS note:

Energetic child + boring school = ADHD overdiagnosis

- Children are not designed to sit for hours in chairs inside.
- The youngest children in a class tend to be more fidgety—and more often diagnosed. [5]
- Older students may seek out stimulant ADHD prescription drugs–"good-grade pills." [6]
- What are the long-term effects of drug treatment?
- Why the increased diagnoses worldwide? [7]

SUPPORTERS note:

- More diagnoses reflect increased awareness.
- "ADHD is a real neurobiological disorder whose existence should no longer be debated." [8]
- ADHD is associated with abnormal brain structure, abnormal brain activity patterns, and future risky or antisocial behavior. [9]

Causes?

- Co-exists with learning disorder or with defiant and temper-prone behavior.
- Genetic [10]

Treatment

- Stimulant drugs (Ritalin and Adderall) calm hyperactivity, and increase ability to sit and focus.[11] So do behavior therapy and aerobic exercise. [12]
- Psychological therapies help with the distress of ADHD. [13]

The bottom line:

Extreme inattention, hyperactivity, and impulsivity can derail social, academic, and work achievements. These symptoms can be treated with medication and other therapies. But the debate continues over whether normal high energy is too often diagnosed as a psychiatric disorder, and whether there is a cost to the long-term use of stimulant drugs in treating ADHD.

Despite their risks, diagnostic labels have benefits. They help mental health professionals to communicate about their cases and to study the causes and treatments of disorders. Clients are often relieved to learn that their suffering has a name, and that they are not alone in experiencing their symptoms.

> “*My sister suffers from a bipolar disorder and my nephew from schizoaffective disorder. There has, in fact, been a lot of depression and alcoholism in my family and, traditionally, no one ever spoke about it. It just wasn’t done. The stigma is toxic.*”
>
> *Actress Glenn Close, “Mental Illness: The Stigma of Silence,” 2009*

Paramount Pictures/Photofest

Better portrayals Old stereotypes are slowly being replaced in media portrayals of psychological disorders. Recent films offer fairly realistic depictions. *Iron Man 3* (2013) portrayed a main character, shown here, with posttraumatic stress disorder.

✓ Check Your Understanding

Ask Yourself

- Do you know someone (could be you) who has been diagnosed with a psychological disorder? How do you think a diagnostic label might help or hurt this person?

Test Yourself

- A lawyer is distressed by feeling the need to wash his hands 100 times a day. He has little time to meet with clients, and his colleagues are wondering about his competence. His behavior would probably be labeled disordered, because it is _______________—that is, it interferes with his day-to-day life.
- Are psychological disorders universal or culture-specific? Explain with examples.
- What is the value, and what are the dangers, of labeling individuals with

disorders?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Does Disorder Equal Danger?

65-5 Do psychological disorders predict violent behavior?

September 16, 2013, started like any other Monday at Washington, DC's, Navy Yard, with people arriving early to begin work. Then government contractor Aaron Alexis entered the building and began shooting. An hour later, 13 people were dead, including the shooter. Reports later confirmed that Alexis had a history of mental illness and had stated that an "ultra low frequency attack is what I've been subject to for the last three months. And to be perfectly honest, that is what has driven me to this." This devastating mass shooting, like the one in a Connecticut elementary school in 2012 and many others since then, reinforced public perceptions that people with psychological disorders pose a threat (Barry et al., 2013; Jorm et al., 2012). "People with mental illness are getting guns and committing these mass shootings," said Speaker of the U.S. House Paul Ryan (2015). In one survey, 84 percent of Americans agreed that "increased government spending on mental health screening and treatment" would be a "somewhat" or "very" effective "approach to preventing mass shootings at schools" (Newport, 2012).

How to prevent mass shootings? Following the Newtown, Connecticut, slaughter of 20 young children and 6 adults, people wondered: Could those at risk for violence be identified in advance by mental health workers and reported to police? Would laws that require such reporting discourage disturbed gun owners from seeking mental health treatment?

Do disorders actually increase risk of violence? And can clinicians predict who is likely to do harm? *No*. Most violent criminals are not mentally ill, and most mentally ill people are not violent (Fazel & Grann, 2006; Skeem et al., 2016). Moreover, clinical prediction of violence is unreliable. The few people with disorders who commit violent acts tend to be either those, like the Navy Yard shooter, who experience threatening delusions and hallucinated voices that command them to act, who have suffered a financial crisis or lost relationship, or who abuse substances (Douglas et al., 2009; Elbogen et al., 2016; Fazel et al., 2009, 2010).

People with disorders are more likely to be *victims* than perpetrators of violence (Marley & Bulia, 2001). According to the U.S. Surgeon General's Office (1999, p. 7), "there is very little risk of violence or harm to a stranger from casual contact with an individual who has a mental disorder." Psychological disorders only rarely lead to violent acts, and focusing gun restrictions only on mentally ill people will likely not reduce gun violence (Friedman, 2012). Better predictors of violence are use of alcohol or drugs, previous violence, and gun availability. The mass-killing shooters have one more thing in common: They tend to be young males.

Whether people with mental disorders who turn violent should be held responsible for their behavior remains controversial. U.S. President Ronald Reagan's near-assassin, John Hinckley, was sent to a hospital rather than to prison. The public was outraged. Others were outraged in 2011, when Jared Lee Loughner killed six people and injured several others, including U.S. Representative Gabrielle Giffords. Loughner was diagnosed with schizophrenia but nevertheless sentenced to life in prison without parole.

AP® EXAM TIP

Notice that the term *insanity* comes out of the legal system. Insanity in criminal law means that defendants cannot be held accountable for their actions, typically due to mental disorder. It is not a psychological or medical diagnosis and does not appear in the DSM-5.

Which decision—hospital or prison—was correct? “My brain . . . my genes . . . my bad upbringing made me do it.” Such defenses were anticipated by Shakespeare’s Hamlet. If I wrong someone when not myself, he explained, “then Hamlet does it not, Hamlet denies it. Who does it then? His madness.” Such is the essence of a legal insanity defense, which asserts that the defendant cannot be held responsible for a criminal act. “Insanity” is a legal rather than a psychological concept, created in 1843 after a deluded Scotsman tried to shoot the prime minister (who he thought was persecuting him) but killed an assistant by mistake. Like Hinckley, Daniel M’Naghten was sent to a mental hospital rather than to prison. In both cases, the public was outraged. “Hinckley Insane, Public Mad,” declared one headline.

As we come to better understand the biological and environmental bases for all human behavior, from generosity to murder, when should we hold people accountable (or not) for their actions? In these situations, psychology and the legal system often work together. Mental health practitioners may be asked to interview and assess offenders and provide their expert opinions, or to discuss an existing client, which may be done only with the client’s approval. (When a person sees a therapist, confidentiality about those sessions is generally assured by the strict rules of the *therapist-patient privilege*.) With this information in hand, judges and juries can make more informed decisions about personal responsibility and accountability.

Rates of Psychological Disorders

65-6 How many people have, or have had, a psychological disorder? Is poverty a risk factor?

Who is most vulnerable to psychological disorders? At what times of life? To answer such questions, many countries have conducted lengthy structured interviews with representative samples of thousands of their citizens. After asking hundreds of questions that probed for symptoms —"Has there ever been a period of two weeks or more when you felt like you wanted to die?"—the researchers have estimated the current, prior-year, and lifetime prevalence of various disorders.

How many people have, or have had, a psychological disorder? More than most of us suppose:

- The U.S. National Institute of Mental Health (2015) has estimated that just under 1 in 5 adult Americans currently have a "mental, behavioral, or emotional disorder (excluding developmental and substance use disorders)" or have had one within the past year (**Table 65.2**).
- A World Health Organization study—based on 90-minute interviews with thousands of people who were representative of their country's population—estimated the number of prior-year mental disorders in 28 countries (Kessler et al., 2009). As **Figure 65.2** illustrates, the lowest rate of reported mental disorders was in Nigeria, the highest rate in the United States. Moreover, immigrants to the United States from Mexico, Africa, and Asia averaged better mental health than their U.S. counterparts with the same ethnic heritage (Breslau et al., 2007; Maldonado-Molina et al., 2011). For example, compared with Mexican-Americans born in the United States, Mexican-Americans who have recently immigrated are less at risk for mental disorders—a phenomenon known as the *immigrant paradox* (Schwartz et al., 2010).

TABLE 65.2 Percentage of Americans Reporting Selected Psychological Disorders in the Past Year

Psychological Disorder	**Percentage**
Depressive disorders or bipolar disorder	9.3
Phobia of specific object or situation	8.7
Social anxiety disorder	6.8
Attention-deficit/hyperactivity disorder (ADHD)	4.1
Posttraumatic stress disorder (PTSD)	3.5
Generalized anxiety disorder	3.1
Schizophrenia	1.1
Obsessive-compulsive disorder	1.0

Data from: National Institute of Mental Health, 2015.

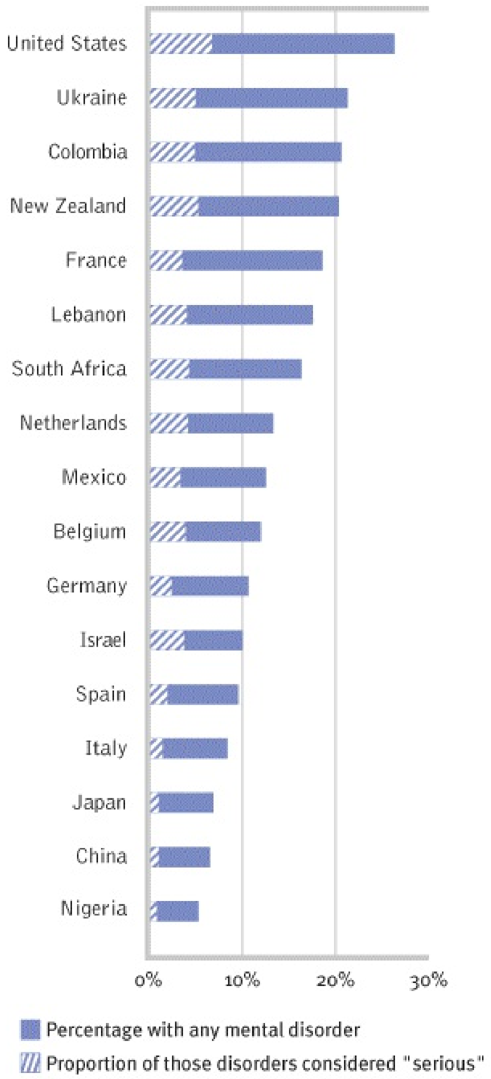

Figure 65.2

Figure 65.2 Prior-year prevalence of disorders in selected areas

From interviews in 28 countries (Kessler et al., 2009).

What increases vulnerability to mental disorders? As **Table 65.3** indicates, there is a wide range of risk and protective factors for mental disorders. But one predictor of mental disorder—poverty—crosses ethnic and gender lines. The incidence of serious psychological disorders is 2.5 times higher among those below the poverty line (CDC, 2014). Like so many other *correlations*, the poverty-disorder association raises further questions: Does poverty cause disorders? Or do disorders cause poverty? It is both, though the answer varies with the disorder. Schizophrenia understandably leads to poverty. Yet the stresses and demoralization of poverty can also precipitate disorders, especially depression in women and substance abuse in men (Dohrenwend et al., 1992). In one natural experiment investigating the poverty-pathology link, researchers tracked rates of behavior problems in North Carolina Native American children as economic development enabled a dramatic reduction in their community's poverty rate. As the study began, children of poverty exhibited more deviant and aggressive behaviors. After four years, children whose families had moved above the poverty line exhibited a 40 percent decrease in behavior problems. Those who maintained their previous positions below or above the poverty line exhibited no change (Costello et al., 2003).

TABLE 65.3 Risk and Protective Factors for Mental Disorders

Risk Factors	Protective Factors
Academic failure Birth complications Caring for those who are chronically ill or who have a neurocognitive disorder Child abuse and neglect Chronic insomnia Chronic pain Family disorganization or conflict Low birth weight Low socioeconomic status Medical illness Neurochemical imbalance Parental mental illness Parental substance abuse Personal loss and bereavement Poor work skills and habits Reading disabilities Sensory disabilities Social incompetence Stressful life events Substance abuse Trauma experiences	Aerobic exercise Community offering empowerment, opportunity, and security Economic independence Effective parenting Feelings of mastery and control Feelings of security High self-esteem Literacy Positive attachment and early bonding Positive parent-child relationships Problem-solving skills Resilient coping with stress and adversity Social and work skills Social support from family and friends

Research from: World Health Organization (WHO, 2004b,c).

At what times of life do disorders strike? Usually by early adulthood. "Over 75 percent of our sample with any disorder had experienced [their] first symptoms by age 24," reported Lee Robins and Darrel Regier (1991, p. 331). Among the earliest to appear are the symptoms of antisocial personality disorder (median age 8) and of phobias (median age 10). Alcohol use disorder, obsessive-compulsive disorder, bipolar disorder, and schizophrenia symptoms appear at a median age near 20. Major depressive disorder often hits somewhat later, at a median age of 25.

✓ Check Your Understanding

Ask Yourself

- How would you draw the line between sending mentally ill criminals to prisons or to psychiatric hospitals? Would the person's history (for example, having suffered child abuse) influence your decision?

Test Yourself

- What is the biopsychosocial approach, and why is it important in our understanding of psychological disorders?
- What is the relationship between poverty and psychological disorders?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 65 REVIEW

65-1 How do we draw the line between normality and disorder?

- According to psychologists and psychiatrists, a *psychological disorder* is a syndrome marked by a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior.
- Disordered thoughts, emotions, or behaviors are dysfunctional or maladaptive, interfering with normal daily life.

65-2 How do the medical model and the biopsychosocial approach influence our understanding of psychological disorders?

- The *medical model* assumes that psychological disorders are mental illnesses with physical causes that can be diagnosed, treated, and, in most cases, cured through therapy, sometimes in a hospital.
- The biopsychosocial approach assumes that three sets of influences—biological, psychological, and social-cultural—interact to produce specific psychological disorders.
- Culture-specific disorders, the vulnerability stress model, and *epigenetics* all provide insight into the ways in which biology and environment interact to make it more or less likely that a psychological disorder will develop.

65-3 How and why do clinicians classify psychological disorders, and why do some psychologists criticize the use of diagnostic labels?

- The American Psychiatric Association's *DSM-5 (Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition) contains diagnostic labels and descriptions that provide a common language and shared concepts for communication and research.

- Classification helps psychiatrists and psychologists to *predict* a disorder’s future course, *suggest* treatment, and *prompt* research into its causes.
- Some critics believe the DSM casts too wide a net and may pathologize normal behaviors. Other critics view DSM diagnoses as arbitrary labels that create preconceptions that bias perceptions of the labeled person’s past and present behavior.

65-4 Why is there controversy over attention-deficit/hyperactivity disorder?

- A child who displays inattention, hyperactivity, and impulsivity may be diagnosed with *attention-deficit/hyperactivity disorder (ADHD)* and treated with medication and other therapy.
- The controversy centers on whether the growing number of ADHD cases reflects overdiagnosis or increased awareness of the disorder. Long-term effects of stimulant-drug treatment for ADHD are not yet known.

65-5 Do psychological disorders predict violent behavior?

- Most violent criminals are not mentally ill, and most mentally ill people are not violent. People with disorders are more likely to be victims than attackers.
- Whether people with mental disorders who become violent should be held responsible for their behavior raises moral and ethical questions. Psychology and law must often work hand-in-hand to determine the best course of action.

65-6 How many people have, or have had, a psychological disorder? Is poverty a risk factor?

- Psychological disorder rates vary, depending on the time and place of the survey. In one multinational survey, rates for any disorder ranged from 6 percent (Nigeria) to 27 percent (the United States).

- Poverty is a risk factor: Conditions and experiences associated with poverty contribute to the development of psychological disorders. But some disorders, such as schizophrenia, can drive people into poverty.

Multiple-Choice Questions

1. Which of the following describes the idea that psychological disorders result from an interplay of a variety of factors?

a. Taijin-kyofusho
b. The DSM–5
c. The biopsychosocial approach
d. Amok
e. The medical model

2. Which of the following is the primary purpose of the DSM–5?

a. Describing mental disorders
b. Selecting appropriate psychological therapies for mental disorders
c. Placing mental disorders in their appropriate cultural context
d. Selecting appropriate medicines to treat mental disorders
e. Understanding the causes of mental disorders

3. The better predictor(s) of violence is (are):

I. Use of alcohol or drugs
II. Previous violence
III. Psychological disorders

a. I & II only
b. II & III only
c. I & III only
d. III only
e. I, II, & III

4. The nation with the highest reported rates of psychological disorders is

a. Ukraine.

b. China.
c. Nigeria.
d. the United States.
e. France.

Practice FRQs

1. Name and describe the two major approaches to understanding psychological disorders.

Answer

2 points: The medical model attempts to first diagnose and then treat psychological disorders. Page 667

2 points: The biopsychosocial approach attempts to understand psychological disorders as an interaction of biological, psychological, and social-cultural factors. Page 668

2. Explain two criticisms of the DSM–5.

(2 points)

Module **66 Anxiety Disorders, Obsessive-Compulsive Disorder, and Posttraumatic Stress Disorder**

LEARNING TARGETS

- **66-1 Contrast generalized anxiety disorder, panic disorder, and phobias.**
- **66-2 Describe *obsessive-compulsive disorder* (*OCD*).**
- **66-3 Describe *posttraumatic stress disorder* (*PTSD*).**
- **66-4 Examine how conditioning, cognition, and biology contribute to the feelings and thoughts that mark anxiety disorders, OCD, and PTSD.**

Anxiety is part of life. Speaking in front of a class, peering down from a ladder, or waiting to play in a big game, any one of us might feel anxious. Anxiety may even cause us to avoid talking or making eye contact —"shyness," we call it. Fortunately for most of us, our uneasiness is not intense and persistent. Some, however, are more prone to fear the unknown and to notice and remember perceived threats (Gorka et al., 2017; Mitte, 2008). When the brain's danger-detection system becomes hyperactive, we are at greater risk for an *anxiety disorder* and for two other disorders that involve anxiety: *obsessive-compulsive disorder (OCD)* and *posttraumatic stress disorder (PTSD).*[1]

Anxiety Disorders

Flip It Video: Anxiety Disorders

66-1 How do generalized anxiety disorder, panic disorder, and phobias differ?

The **anxiety disorders** are marked by distressing, persistent anxiety or by dysfunctional anxiety-reducing behaviors. For example, people with **social anxiety disorder** become extremely anxious in social settings where others might judge them, such as parties, class presentations, or even eating in public. To stave off anxious thoughts and feelings (including physical symptoms such as sweating and trembling), they may avoid going out at all. Even though this behavior reduces their anxiety, it is maladaptive—it does not help them cope with their world.

anxiety disorders

psychological disorders characterized by distressing, persistent anxiety or maladaptive behaviors that reduce anxiety.

social anxiety disorder

intense fear and avoidance of social situations. (Formerly called *social phobia*.)

Let’s take a closer look at three other anxiety disorders:

- *Generalized anxiety disorder*, in which a person is unexplainably and continually tense and uneasy.
- *Panic disorder*, in which a person experiences *panic attacks*—sudden episodes of intense dread—and fears the next episode’s unpredictable onset.
- *Phobias*, in which a person is intensely and irrationally afraid of a specific object, activity, or situation.

Generalized Anxiety Disorder

For two years, Tom, a 27-year-old electrician, was bothered by dizziness, sweating palms, and heart palpitations. He felt on edge and sometimes found himself shaking. Tom was fairly successful in hiding his symptoms from his family and co-workers. But he allowed himself few other social contacts, and occasionally he had to leave work. Neither his family doctor nor a neurologist was able to find any physical problem.

Tom’s unfocused, out-of-control, agitated feelings suggest **generalized anxiety disorder**, which is marked by excessive and uncontrollable worry that persists for six months or more. People with this condition (two-thirds are women) worry continually, and they are often jittery, agitated, and sleep-deprived (McLean & Anderson, 2009). Their gaze becomes fixated on potential threats (Pergamin-Hight et al., 2015). Concentration is difficult as attention switches from worry to worry. Their tension and apprehension may leak out through furrowed brows, twitching eyelids, trembling, perspiration, or fidgeting from *autonomic nervous system* arousal.

generalized anxiety disorder

an anxiety disorder in which a person is continually tense, apprehensive, and in a state of autonomic nervous system arousal.

The person usually cannot identify, and therefore relieve or avoid, the tension’s cause. To use Sigmund Freud’s term, the anxiety is *free-floating* (not linked to a specific stressor or threat). Generalized anxiety disorder is often accompanied by depressed mood, but even without depression it tends to be disabling (Hunt et al., 2004; Moffitt et al., 2007). Moreover, it may lead to physical problems, such as high blood pressure. As time passes, however, emotions tend to mellow, and by age 50, generalized anxiety disorder becomes fairly rare (Rubio & López-Ibor, 2007).

Panic Disorder

Many people can experience an intense anxiety that escalates into a terrifying panic attack—a minutes-long episode of intense fear that something horrible is about to happen. Irregular heartbeat, chest pains, shortness of breath, choking, trembling, or dizziness may accompany the panic. One woman recalled suddenly feeling

> hot and as though I couldn't breathe. My heart was racing and I started to sweat and tremble and I was sure I was going to faint. Then my fingers started to feel numb and tingly and things seemed unreal. It was so bad I wondered if I was dying and asked my husband to take me to the emergency room. By the time we got there (about 10 minutes) the worst of the attack was over and I just felt washed out (Greist et al., 1986).

For the 3 percent of people with **panic disorder**, panic attacks are recurrent. These anxiety tornados strike suddenly, wreak havoc, and disappear, but are not forgotten. Ironically, worries about anxiety—perhaps fearing another panic attack, or fearing anxiety-related symptoms in public—can amplify anxiety symptoms (Olatunji & Wolitzky-Taylor, 2009). After several panic attacks, people may avoid situations where panic might strike. If their fear is intense enough, people may develop **agoraphobia**—fear or avoidance of public situations from which escape might be difficult. Given such fear, people may avoid being outside the home, in a crowd, or in an elevator. Smokers have at least a doubled risk of panic disorder and greater symptoms when they do have an attack (Knuts et al., 2010; Zvolensky & Bernstein, 2005). Because nicotine is a stimulant, lighting up doesn't lighten us up.

panic disorder

an anxiety disorder marked by unpredictable, minutes-long episodes of intense dread in which a person may experience terror and accompanying chest pain, choking, or other frightening sensations; often followed by worry over a possible next attack.

agoraphobia

fear or avoidance of situations, such as crowds or wide open places, where one has felt loss of control and panic.

Charles Darwin began suffering from panic disorder at age 28, after spending five years sailing the world. He moved to the country, avoided social gatherings, and traveled only in his wife’s company. But the relative seclusion did free him to develop his evolutionary theory. “Even ill health,” he reflected, “has saved me from the distraction of society and its amusements” (quoted in Ma, 1997).

Sam Greenwood/Getty Images

Panic on the course Golfer Charlie Beljan experienced what he later learned were panic attacks during an important tournament. His thumping heartbeat and shortness of breath led him to think he was having a heart attack. But hospital tests revealed that his symptoms were not related to a physical illness. He recovered, went on to win $846,000, and has become an inspiration to others.

Phobias

We all live with some fears. But people with **phobias** are consumed by a persistent, irrational fear and avoidance of some object, activity, or situation. *Specific phobias* may focus on animals, insects, heights, blood, or close spaces (**Figure 66.1**). Many people avoid the triggers (such as high places) that arouse their fear, and they manage to live with their phobia. Others are incapacitated by their efforts to avoid the feared situation. Marilyn, an otherwise healthy and happy 28-year-old, so feared thunderstorms that she felt anxious as soon as a weather forecaster mentioned possible storms later in the week. If her husband was away when a storm was forecast, she often stayed with a close relative. During a storm, she hid from windows and buried her head to avoid seeing the lightning.

phobia

an anxiety disorder marked by a persistent, irrational fear and avoidance of a specific object, activity, or situation.

Figure 66.1 Some common and uncommon specific fears

Researchers surveyed Dutch people to identify the most common events or objects they feared. A strong fear becomes a phobia if it provokes a compelling but irrational desire to avoid the dreaded object or situation.

Check Your Understanding

Ask Yourself

- Have you ever seen a movie or TV character exhibit anxiety disorder symptoms? Based on what you've read, how realistic was the portrayal of the disorder?

Test Yourself

- Unfocused tension, apprehension, and arousal are symptoms of _______________ _______________ disorder.
- Those who experience unpredictable periods of terror and intense dread, accompanied by frightening physical sensations, may be diagnosed with a

_______________ disorder.

- If a person is focusing anxiety on specific feared objects or situations, that person may have a _______________.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Obsessive-Compulsive Disorder (OCD)

66-2 What is OCD?

As with the anxiety disorders, we can see aspects of **obsessive-compulsive disorder (OCD)** in our everyday behavior. *Obsessive thoughts* are unwanted and so repetitive it may seem they will never go away. *Compulsive behaviors* are often responses to those thoughts.

obsessive-compulsive disorder (OCD)
a disorder characterized by unwanted repetitive thoughts (obsessions), actions (compulsions), or both.

We are all at times obsessed with thoughts, and we may behave compulsively. Have you ever felt a bit anxious about how your living space will appear to others and found yourself checking and cleaning one last time before your guests arrived? Or, perhaps worried about an upcoming test, you caught yourself lining up books or devices "just so" before you began studying? Our lives are full of little rehearsals and fussy behaviors. They cross the fine line between normality and disorder when they *persistently interfere* with everyday living and cause distress. Checking that you locked the door is normal; checking 10 times is not. Washing your hands is normal; washing so often that your skin becomes raw is not. (**Table 66.1** offers more examples.) At some time during their lives, often during their late teens or twenties, about 2 percent of people cross that line from normal preoccupations and fussiness to debilitating disorder (Kessler et al., 2012). Although people know their anxiety-fueled obsessive thoughts are irrational, these thoughts can become so haunting, and the compulsive rituals so senselessly time-consuming, that effective functioning becomes impossible.

TABLE 66.1 Common Obsessions and Compulsions Among Children and Adolescents With Obsessive-Compulsive Disorder

and Adolescents With Obsessive-Compulsive Disorder

Thought or Behavior	Percentage Reporting Symptom
Obsessions (repetitive *thoughts*)	
Concern with dirt, germs, or toxins	40
Something terrible happening (fire, death, illness)	24
Symmetry, order, or exactness	17
Compulsions (repetitive *behaviors*)	
Excessive hand washing, bathing, toothbrushing, or grooming	85
Repeating rituals (in/out of a door, up/down from a chair)	51
Checking doors, locks, appliances, car brakes, homework	46

Data from: Rapoport, 1989.

OCD is more common among teens and young adults than among older people (Samuels & Nestadt, 1997). A 40-year follow-up study of 144 Swedish people diagnosed with the disorder found that, for most, the obsessions and compulsions had gradually lessened, though only 1 in 5 had completely recovered (Skoog & Skoog, 1999).

Michael Campanella/WireImage/Getty Images

Thriving with OCD Music star Justin Timberlake has openly discussed his obsessive-compulsive disorder. He says that support from family and a rich sense of humor have helped him cope with the challenges.

Some people experience other OCD-related disorders, such as *hoarding disorder* (cluttering one's space with acquired possessions one can't let go), *body dysmorphic disorder* (preoccupation with perceived body defects), or—new words to impress your friends—*trichotillomania* (hair-pulling) or *excoriation disorder* (excessive skin-picking).

Posttraumatic Stress Disorder (PTSD)

66-3 What is PTSD?

While serving his country in war, one soldier, Jesse, saw the killing “of children and women. It was just horrible for anyone to experience.” Back home, he suffered “real bad flashbacks” (Welch, 2005).

Jesse is not alone. In one study of 103,788 veterans returning from Iraq and Afghanistan, 25 percent were diagnosed with a psychological disorder (Seal et al., 2007). Some had *traumatic brain injuries* (*TBI)*, but the most frequent diagnosis was **posttraumatic stress disorder (PTSD)**. Survivors of accidents, disasters, and violent and sexual assaults (including an estimated two-thirds of prostitutes) have also experienced PTSD symptoms (Brewin et al., 1999; Guo et al., 2017; Farley et al., 1998). Typical symptoms include recurring haunting memories and nightmares, laser-focused attention to possible threats, social withdrawal, jumpy anxiety, and trouble sleeping (Germain, 2013; Hoge et al., 2007; Yuval et al., 2017).

posttraumatic stress disorder (PTSD)

a disorder characterized by haunting memories, nightmares, hypervigilance, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia that lingers for four weeks or more after a traumatic experience.

About half of us will experience at least one traumatic event in our lifetime. And many people will display *survivor resiliency*—by recovering after severe stress (Bonanno, 2004, 2005; Infurna & Luthar, 2016). Although Friedrich Nietzsche’s (1889) surmise that “what does not kill me makes me stronger” is not true for all, some will even experience *posttraumatic growth* (see Unit XIII). Why do some 5 to 10 percent of people develop PTSD after a traumatic event, but others don’t (Bonanno et al., 2011)? One factor seems to be the amount of trauma-related emotional distress: The higher the distress, such as the level of physical torture suffered by prisoners of war, the greater the risk for posttraumatic symptoms (King et al., 2015; Ozer et al., 2003). Among American military personnel in Afghanistan, 7.6 percent of combatants developed PTSD, compared with 1.4 percent of noncombatants (McNally, 2012). Among survivors of the 9/11 terrorist attacks on New York's World Trade Center, the rates of subsequent PTSD diagnoses for those who had been inside were double the rates of those who had been outside (Bonanno et al., 2006).

LYNN JOHNSON/National Geographic Creative

Bringing the war home Hundreds of thousands of Iraq and Afghanistan war veterans have been diagnosed with PTSD or traumatic brain injury (TBI) (VA, 2017). Many vets participate in an intensive recovery program using deep breathing, massage, and group and individual discussion techniques to treat their PTSD or TBI.

What else can influence PTSD development? Some people may have a more sensitive emotion-processing limbic system that floods their bodies with stress hormones, which explains why PTSD may coexist with another disorder (Duncan et al., 2017; Kosslyn, 2005; Ozer & Weiss, 2004). Genes and gender also matter. Twins, compared with nontwin siblings, more commonly share PTSD cognitive risk factors (Gilbertson et al., 2006). And the odds of experiencing PTSD after a traumatic event are about two times higher for women than for men (Olff et al., 2007; Ozer & Weiss, 2004).

Some psychologists believe that PTSD has been overdiagnosed (Dobbs, 2009; McNally, 2003). Too often, say critics, PTSD gets stretched to include normal stress-related bad memories and dreams. And some well-intentioned procedures—such as “debriefing” people by asking them to revisit the experience and vent their emotions—may worsen stress reactions (Bonanno et al., 2010; Wakefield & Spitzer, 2002). Other research shows that reliving traumas (such as 9/11 or the Boston Marathon bombing) through media coverage sustains the stress response (Holman et al., 2014).

✓ Check Your Understanding

Ask Yourself

- Have you ever experienced obsessive thoughts or compulsive behaviors? Did they interfere with your day-to-day functioning?

Test Yourself

- Those who express anxiety through unwanted repetitive thoughts or actions may have a(n) ______________-______________ disorder.
- Those with symptoms of recurring memories and nightmares, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia for weeks after a traumatic event may be diagnosed with ______________ ______________ disorder.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Understanding Anxiety Disorders, OCD, and PTSD

66-4 How do conditioning, cognition, and biology contribute to the feelings and thoughts that mark anxiety disorders, OCD, and PTSD?

Anxiety is both a feeling and a cognition—a doubt-laden appraisal of one’s safety or social skill. How do these anxious feelings and cognitions arise? Sigmund Freud’s psychoanalytic theory proposed that, beginning in childhood, people *repress* intolerable impulses, ideas, and feelings. Freud believed that this submerged mental energy sometimes leaks out in odd symptoms, such as anxious handwashing. Few of today’s psychologists share Freud’s interpretation of anxiety. Most believe that three modern perspectives—conditioning, cognition, and biology—are more helpful.

AP® EXAM TIP

The AP® Exam may also include references to the *psychoanalytic* and *humanistic* approaches to explaining psychological disorders. Relatively few modern therapists make use of these historically important approaches (see Module 70).

Conditioning

Through *classical conditioning*, our fear responses can become linked with formerly neutral objects and events. In a classic experiment, an infant—“Little Albert”—learned to fear furry objects that researchers paired with loud noises (see Module 26). In other experiments, researchers have created anxious animals by giving rats unpredictable electric shocks (Schwartz, 1984). The rats, like assault victims who report feeling anxious when returning to the scene of the crime, had learned to become uneasy in their lab environment. The lab had become a cue for fear.

AP® EXAM TIP

This is a good time to review Unit I, specifically, the behavioral, biological, cognitive, and evolutionary perspectives. Be able to discuss what these approaches focus on and how they explain behavior.

Such research helps explain why anxious or traumatized people learn to associate their anxiety with certain cues (Bar-Haim et al., 2007; Duits et al., 2015). In one survey, 58 percent of those with social anxiety disorder experienced their disorder after a traumatic event (Ost & Hugdahl, 1981). Anxiety or an anxiety-related disorder is more likely to develop when bad events happen unpredictably and uncontrollably (Field, 2006; Mineka & Oehlberg, 2008). Even a single painful and frightening event may trigger a full-blown phobia, thanks to two conditioning processes: classical conditioning's *stimulus generalization* and operant conditioning's *reinforcement.*

Stimulus generalization occurs when a person experiences a fearful event and later develops a fear of similar events. My [DM's] car was once struck by a driver who missed a stop sign. For months afterward, I felt a twinge of unease when any car approached from a side street. Likewise, I [ND] was watching a terrifying movie about spiders, *Arachnophobia*, when a severe thunderstorm struck and the theater lost power. For months, I experienced anxiety at the sight of spiders or cobwebs. Those fears eventually disappeared, but sometimes fears linger and grow. Marilyn's thunderstorm phobia may have similarly generalized after a terrifying or painful experience during a thunderstorm.

AP® EXAM TIP

Review time: Think about the reinforcement examples provided here. Do they describe *positive* or *negative* reinforcement?[2]

Reinforcement helps maintain learned fears and anxieties. Anything that enables us to avoid or escape a feared situation can reinforce maladaptive behaviors. Fearing a panic attack, we may decide not to leave the house. Reinforced by feeling calmer, we are likely to repeat that behavior in the future (Antony et al., 1992). So, too, with compulsive behaviors. If washing our hands relieves our feelings of anxiety, we may wash our hands again when those feelings return.

Cognition

Conditioning influences our feelings of anxiety, but so does cognition—our thoughts, memories, interpretations, and expectations. By observing others, we can learn to fear what they fear. Nearly all monkeys raised in the wild fear snakes, yet lab-raised monkeys do not. Surely, most wild monkeys do not actually suffer snake bites. Do they learn their fear through observation? To find out, Susan Mineka (1985, 2002) experimented with six monkeys raised in the wild (all strongly fearful of snakes) and their lab-raised offspring (virtually none of which feared snakes). After repeatedly observing their parents or peers refusing to reach for food in the presence of a snake, the younger monkeys developed a similar strong fear of snakes. When the monkeys were retested three months later, their learned fear persisted. We humans similarly learn many of our own fears by observing others (Helsen et al., 2011; Olsson et al., 2007).

Hemera Technologies/PhotoObjects.net/360/Getty Images

Our past experiences shape our expectations and influence our interpretations and reactions. Whether we interpret the creaky sound simply as the wind or as a possible knife-wielding attacker determines whether we panic. People with anxiety disorders tend to be *hypervigilant*. They *attend* more to threatening stimuli. They more often *interpret* unclear stimuli as threatening: A pounding heart signals a heart attack; a lone spider near the bed indicates a likely infestation; an everyday disagreement with a friend or boss spells doom for the relationship. And they more often *remember* threatening events (Van Bockstaele et al., 2014). Anxiety is especially common when people cannot switch off such intrusive thoughts and perceive a loss of control and a sense of helplessness (Franklin & Foa, 2011).

Biology

There is, however, more to anxiety disorders, OCD, and PTSD than conditioning and cognitive processes alone. Why do some of us develop lasting phobias or PTSD after suffering traumas, but others do not? Why do we all learn some fears so readily than others? The answers lie in part in our biology.

Genes

Among monkeys, fearfulness runs in families. A monkey reacts more strongly to stress if its close biological relatives are anxiously reactive (Suomi, 1986). So, too, with people. If one identical twin has an anxiety disorder, the other is also at risk (Polderman et al., 2015). Even when raised separately, identical twins may develop similar phobias (Carey, 1990; Eckert et al., 1981). One pair of 35-year-old identical twins independently became so afraid of water that each would wade in the ocean backward and only up to her knees.

Given the genetic contribution to anxiety disorders, researchers are sleuthing the culprit genes. One research team identified 17 gene variations associated with typical anxiety disorder symptoms (Hovatta et al., 2005). Other teams have found genes associated specifically with OCD (Mattheisen et al., 2015; Taylor, 2013).

Some genes influence disorders by regulating brain levels of neurotransmitters. These include *serotonin*, which influences sleep, mood, and attending to threats (Canli, 2008; Pergamin-Hight et al., 2012), and *glutamate*, which heightens activity in the brain's alarm centers (Lafleur et al., 2006; Welch et al., 2007).

So genes matter. Some of us have genes that make us like orchids—fragile, yet capable of beauty under favorable circumstances. Others of us are like dandelions—hardy, and able to thrive in varied circumstances (Ellis & Boyce, 2008; Pluess & Belsky, 2013).

But experience affects gene expression. Among those with PTSD, a history of child abuse leaves long-term *epigenetic marks*, which are often organic molecules. These molecular tags attach to our chromosomes and turn certain genes on or off. Thus, experiences such as abuse can increase the likelihood that a genetic vulnerability to a disorder will be expressed (Mehta et al., 2013; Zannas et al., 2015). People who commit suicide show a similar epigenetic effect (Lockwood et al., 2015; McGowan et al., 2009).

The Brain

Our experiences change our brain, paving new pathways. Traumatic fear-learning experiences can leave tracks in the brain, creating fear circuits within the amygdala (Etkin & Wager, 2007; Herringa et al., 2013; Kolassa & Elbert, 2007). These fear pathways create easy inroads for more fear experiences (Armony et al., 1998).

Generalized anxiety disorder, panic attacks, phobias, OCD, and PTSD express themselves biologically as overarousal of brain areas involved in impulse control and habitual behaviors. These disorders reflect a brain danger-detection system gone hyperactive—producing anxiety when no danger exists. In OCD, for example, when the brain detects that something is amiss, it seems to generate a mental hiccup of repeating thoughts (obsessions) or actions (compulsions) (Gehring et al., 2000). Brain scans of people with PTSD show higher-than-normal activity in the amygdala when they view traumatic images (Etkin & Wager, 2007). Brain scans of people with OCD reveal elevated activity in specific brain areas during behaviors such as compulsive hand washing, checking, ordering, or hoarding (Insel, 2010; Mataix-Cols et al., 2004, 2005). The *anterior* *cingulate cortex,* a brain region that monitors our actions and checks for errors, seems especially likely to be hyperactive (Maltby et al., 2005) (**Figure 66.2**).

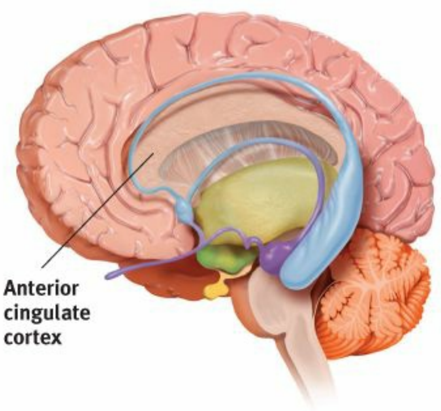

Figure 66.2

Course, 3e, © 2018 Worth Publishers

Figure 66.2 An obsessive-compulsive brain

When people engaged in a challenging cognitive task, those with OCD showed the most activity in the anterior cingulate cortex in the brain's frontal area (Maltby et al., 2005).

Some antidepressant drugs dampen this fear-circuit activity and its associated obsessive-compulsive behavior. Fears can also be blunted by giving people drugs as they recall and then rerecord ("reconsolidate") a traumatic experience (Kindt et al., 2009; Norberg et al., 2008). Although they don't forget the experience, the associated emotion is largely erased.

Natural Selection

We seem biologically prepared to fear threats faced by our ancestors. Our phobias focus on such specific fears: spiders, snakes, and other animals; enclosed spaces and heights; storms and darkness. Those fearless about these occasional threats were less likely to survive and leave descendants. Even in Britain, with only one poisonous snake species, people often fear snakes. Nine-month-old infants attend more to sounds signaling ancient threats (hisses, thunder) than they do to sounds representing modern dangers (a bomb exploding, breaking glass) (Erlich et al., 2013). It is easy to condition and hard to extinguish fears of such "evolutionarily relevant" stimuli (Coelho & Purkis, 2009; Davey, 1995; Öhman, 2009). Some of our modern fears can also have an evolutionary explanation. A fear of flying may be rooted in our biological predisposition to fear confinement and heights.

Peter Bohler/Redux Pictures

Fearless The biological perspective helps us understand why most people have more fear of heights than does Alex Honnold, shown here in 2017 becoming the first person to free solo climb (no safety ropes) Yosemite National Park's El Capitan granite wall.

Compare our easy-to-learn fears with those we *do not* easily learn. World War II air raids, for example, produced remarkably few lasting phobias. As the air blitzes continued, the British, Japanese, and German populations did not become more and more panicked. Rather, they grew increasingly indifferent to planes outside their immediate neighborhoods (Mineka & Zinbarg, 1996). Evolution has not prepared us to fear bombs dropping from the sky.

Just as our phobias focus on dangers faced by our ancestors, our compulsive acts typically exaggerate behaviors that contributed to our species' survival. Grooming had survival value. Gone wild, it becomes compulsive hair pulling. So too with washing up, which becomes ritual hand washing. And checking territorial boundaries becomes checking and rechecking already locked doors (Rapoport, 1989). Although natural selection shaped our behaviors, when taken to an extreme, these behaviors can interfere with daily life.

✓ Check Your Understanding

Ask Yourself

- Can you recall a fear that you have learned? What role did conditioning or cognition play?

Test Yourself

- Researchers believe that conditioning and cognitive processes contribute to anxiety-related disorders. What biological factors also contribute to these disorders?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 66 REVIEW

66-1 How do generalized anxiety disorder, panic disorder, and phobias differ?

- Anxious feelings and behaviors are classified as an *anxiety disorder* when they form a pattern of distressing, persistent anxiety or maladaptive behaviors that reduce anxiety.
- People with *generalized anxiety disorder* feel persistently and uncontrollably tense and apprehensive for no apparent reason.
- In the more extreme *panic disorder*, anxiety escalates into periodic episodes of intense dread.
- Those with a *phobia* may be irrationally afraid of a specific object, activity, or situation.

66-2 What is *OCD?*

- Persistent and repetitive thoughts (obsessions) and behaviors (compulsions) characterize *obsessive-compulsive disorder (OCD).*

66-3 What is *PTSD?*

- Symptoms of *posttraumatic stress disorder (PTSD)* include haunting memories, nightmares, social withdrawal, jumpy anxiety, and sleep problems following some traumatic experience.

66-4 How do conditioning, cognition, and biology contribute to the feelings and thoughts that mark anxiety disorders, OCD, and PTSD?

- Through conditioning, anxious or traumatized people may learn to associate their anxiety with certain cues. *Stimulus generalization* occurs when someone experiences a fearful event and later develops a fear of similar events. *Reinforcement* helps maintain learned fears and anxieties.

- Cognition can influence our expectations and our interpretation of and reaction to stimuli. We may learn some fears by observing others' fears. People with anxiety disorders tend to be hypervigilant: They attend more to threatening stimuli, more often interpret ambiguous stimuli as threatening, and remember threatening events.
- Our biology also plays a role. Genetic predispositions for high levels of emotional reactivity and neurotransmitter production make us vulnerable to disorder, as do epigenetic marks. Abnormal responses in the brain's fear circuits can create inroads for disorder. Natural selection and evolution have prepared us to fear the threats our ancestors faced.

Multiple-Choice Questions

1. Andrew is so afraid of spiders that he is having a hard time leaving his "spider-proofed" home and going to work. Andrew's psychiatrist has diagnosed him with

a. agoraphobia.
b. a phobia.
c. panic disorder.
d. generalized anxiety disorder.
e. posttraumatic stress disorder.

2. Leo is always so worried that something bad is about to happen that he can't stay focused at school. A therapist might best diagnose Leo with

a. panic disorder.
b. a phobia.
c. obsessive-compulsive disorder.
d. generalized anxiety disorder.
e. susto.

3. In obsessive-compulsive disorder, obsessions are repetitive _________, and compulsions are repetitive __________.

a. behaviors; thoughts
b. behaviors; experiences
c. thoughts; behaviors
d. concerns; memories
e. thoughts; concerns

4. Which area of the brain exhibits higher-than-normal activity in many people with PTSD?

a. Amygdala
b. Hippocampus
c. Hypothalamus
d. Reticular formation
e. Occipital lobe

5. Rebekah has grown increasingly nervous about going to school and social gatherings. When she is assigned a presentation in English class, she is so terrified that her teacher and classmates will judge her harshly that she can't bring herself to go to school at all. A therapist would be most likely to diagnose her with

a. ADHD.
b. panic disorder.
c. obsessive-compulsive disorder.
d. social anxiety disorder.
e. posttraumatic stress disorder.

Practice FRQs

1. Using psychological terminology, describe how each of the following perspectives helps us understand anxiety disorders, OCD, and PTSD:

- Conditioning
- Cognition
- Biology

Answer

1 point: The conditioning perspective would consider how a person could learn debilitating fears of various objects and situations. This might happen by way of *reinforcement*, when the behavior of avoiding a feared stimulus is reinforced by reduced anxiety, or *stimulus generalization*, when a person experiences a fearful situation and then generalizes that fear to similar stimuli. Pages 681–682

1 point: The cognition perspective would consider how expectations and interpretations might cause a person to overreact to stimuli, and how people may learn some fears by observing others’ fears. Page 682

1 point: The biology perspective would consider how genetic predispositions, epigenetic marks, abnormal brain responses, and natural selection could make us vulnerable to the development of these disorders. Pages 683–684

2. Steve recently lost his job. For each of the disorders below, explain how that diagnosis could have affected his job performance:

- Agoraphobia
- Panic disorder
- Obsessive-compulsive disorder

(3 points)

Module **67 Depressive Disorders, Bipolar Disorder, Suicide, and Self-Injury**

LEARNING TARGETS

- **67-1 Contrast major depressive disorder, persistent depressive disorder, and bipolar disorder.**
- **67-2 Analyze how the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorder.**
- **67-3 Explain what factors increase the risk of suicide, and discuss what we know about nonsuicidal self-injury.**

67-1 How do major depressive disorder, persistent depressive disorder, and bipolar disorder differ?

In the past year, have you at some time “felt so depressed that it was difficult to function”? If so, you were not alone. In one national survey, 31 percent of American college students answered *Yes* (ACHA, 2009). In a survey of American high school students, 29 percent “felt so sad or hopeless almost every day for 2 or more weeks in a row that they stopped doing some usual activities” (CDC, 2008). You might feel deeply discouraged about the future, dissatisfied with your life, or socially isolated. You may lack the energy to get things done, to see people, or even to force yourself out of bed. You may be unable to concentrate, eat, or sleep normally. You may even wonder if you would be better off dead.

Perhaps academic success came easily to you in middle school, but now you find that disappointing grades jeopardize your goals. Maybe social stress, such as loneliness, feeling you are the target of prejudice, or experiencing a romantic breakup, has plunged you into despair. And perhaps low self-esteem increases your brooding, worsening your self-torment (Orth et al., 2016). Likely you think you are more alone in having such negative feelings than you really are (Jordan et al., 2011). Most of us have had some direct or indirect experience with depression: Misery has more company than most suppose.

> “*My life had come to a sudden stop. I was able to breathe, to eat, to drink, to sleep. I could not, indeed, help doing so; but there was no real life in me.*”
>
> *Leo Tolstoy,* My Confession, *1887*

Joy, contentment, sadness, and despair exist at different points on a continuum, points at which any of us may find ourselves at any given moment. To feel bad in reaction to profoundly sad events is to be in touch with reality. In such times, sadness is like a car’s low-fuel light—a warning signal that we should stop and take appropriate measures. Biologically speaking, life’s purpose is not happiness but survival and reproduction. Coughing, vomiting, swelling, and pain protect the body from dangerous toxins and stimuli. Similarly, depression resembles a sort of psychic hibernation: It slows us down, prompting us, when losing a relationship or blocked from a goal, to conserve energy (Beck & Bredemeier, 2016; Gershon et al., 2016). There is sense to suffering. When we grind temporarily to a halt and reassess our life, as depressed people do, we can redirect our energy in more promising ways (Watkins, 2008). Even mild sadness helps people process and recall faces more accurately (Hills et al., 2011). They also tend to pay more attention to details, think more critically (with less gullibility), and make better decisions (Forgas, 2009, 2013).

> “*If someone offered you a pill that would make you permanently happy, you would*

be well advised to run fast and run far. Emotion is a compass that tells us what to do, and a compass that is perpetually stuck on NORTH is worthless.”

Daniel Gilbert, “The Science of Happiness,” 2006

But sometimes this response, taken to an extreme, can become seriously maladaptive and signal a disorder. The difference between a blue mood after bad news and a depression-related disorder is like the difference between breathing heavily after a hard run and being chronically exhausted.

Brad Wenner/Getty Images

In this section, we consider three disorders in which depression impairs daily living, focusing on the two principal forms (formerly known as *mood disorders*). *Major depressive disorder* is a state of hopelessness and lethargy lasting several weeks or months. *Persistent depressive disorder* is similar, but with milder depressive symptoms that last a much longer period of time. *Bipolar disorder (*formerly called *manic-depressive disorder*) is when a person alternates between depression and overexcited hyperactivity.

Major Depressive Disorder

Major depressive disorder occurs when at least five signs of depression (including either depressed mood or loss of interest or pleasure) last two or more weeks (**Table 67.1**). To sense what major depressive disorder feels like, imagine combining the anguish of grief with the sluggishness of bad jet lag. If stress-related anxiety is a “crackling, menacing brushfire,” noted biologist Robert Sapolsky (2003), “depression is a suffocating heavy blanket thrown on top of it.”

major depressive disorder

a disorder in which a person experiences, in the absence of drugs or another medical condition, two or more weeks with five or more symptoms, at least one of which must be either (1) depressed mood or (2) loss of interest or pleasure.

TABLE 67.1 Diagnosing Major Depressive Disorder

The DSM-5 classifies major depressive disorder as the presence of at least five of the following symptoms over a two-week period of time (minimally including depressed mood or reduced interest) (American Psychiatric Association, 2013).
• Depressed mood most of the time
• Dramatically reduced interest or enjoyment in most activities most of the time
• Significant challenges regulating appetite and weight
• Significant challenges regulating sleep
• Physical agitation or lethargy
• Feeling listless or with much less energy
• Feeling worthless, or feeling unwarranted guilt
• Problems in thinking, concentrating, or making decisions
• Thinking repetitively of death and suicide

Adults diagnosed with persistent depressive disorder (also called *dysthymia*) have experienced a mildly depressed mood more often than not for two years or more (American Psychiatric Association, 2013). They also display at least two of the following symptoms:

- Difficulty with decision making and concentration
- Feeling hopeless
- Poor self-esteem
- Reduced energy levels
- Problems regulating sleep
- Problems regulating appetite

Depression is the number-one reason people seek mental health services. Indeed, the World Health Organization declared depression “the top cause of disability in the world today” (CBC, 2017; WHO, 2017b). In one survey conducted in 21 countries, 4.6 percent of people interviewed were experiencing moderate or severe depression (Thornicroft et al., 2017).

For some people, depressive symptoms may have a *seasonal pattern,* returning each winter. When asked “Have you cried today?” Americans have agreed more often in the winter (**Table 67.2**). But some researchers have found that people in northerly or cloudier places do not experience more wintertime depression, and question how often seasonal depression occurs (Traffanstedt et al., 2016). So stay tuned.

TABLE 67.2 Percentage Answering *Yes* When Asked “Have You Cried Today?”

	Percentage who cried	
	Men	Women
August	4%	7%
December	8%	21%

Data from: Time/CNN survey, 1994.

Bipolar Disorder

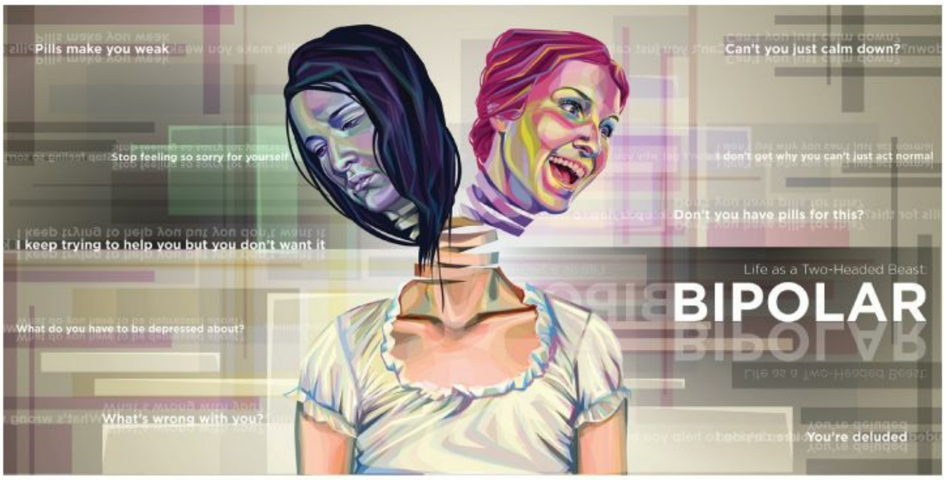
Our genes dispose some of us, more than others, to respond emotionally to good and bad events (Whisman et al., 2014). In **bipolar disorder**, people bounce from one emotional extreme to the other (week to week, rather than day to day or moment to moment). When a depressive episode ends, a euphoric, overly talkative, wildly energetic, and extremely optimistic state called **mania** follows. But before long, the mood either returns to normal or plunges again into depression.

bipolar disorder

a disorder in which a person alternates between the hopelessness and lethargy of depression and the overexcited state of mania. (Formerly called *manic-depressive disorder*.)

mania

a hyperactive, wildly optimistic state in which dangerously poor judgment is common.



Pills make you weak
Can't you just calm down?
Stop feeling so sorry for yourself
I don't get why you can't just act normal
Don't you have pills for this?
I keep trying to help you but you don't want it
Life as a Two-Headed Beast
BIPOLAR
What do you have to be depressed about?
What's wrong with you?
You're deluded

Life as a Two-Headed Beast: Bipolar, Abigail Southworth

Bipolar disorder Artist Abigail Southworth illustrated her experience of bipolar disorder.

During the manic phase, people with bipolar disorder typically have little need for sleep. They show fewer sexual inhibitions. Their positive emotions persist abnormally (Gruber, 2011; Gruber et al., 2013). Their speech is loud, flighty, and hard to interrupt. They find advice irritating. Yet they need protection from their own poor judgment, which may lead to reckless spending or unsafe sex. Thinking fast feels good, but it also increases risk taking (Chandler & Pronin, 2012; Pronin, 2013).

In milder forms, mania’s energy and flood of ideas can fuel creativity. Clusters of genes associated with high creativity increase the likelihood of having bipolar disorder, and risk factors for developing bipolar disorder predict greater creativity (Baas et al., 2016; Power et al., 2015). George Frideric Handel, who may have suffered from a mild form of bipolar disorder, composed his nearly four-hour-long *Messiah* (1742) during three weeks of intense creative energy (Keynes, 1980). Robert Schumann composed 51 musical works during two years of mania (1840 and 1849) but none during 1844, when he was severely depressed (Slater & Meyer, 1959). Those who rely on precision and logic, such as architects, designers, and journalists, suffer bipolar disorder less often than do those who rely on emotional expression and vivid imagery (Ludwig, 1995). Composers, artists, poets, novelists, and entertainers seem especially prone (Jamison, 1993, 1995; Kaufman & Baer, 2002; Ludwig, 1995). Indeed, one analysis of over a million individuals showed that the only psychiatric condition linked to working in a creative profession was bipolar disorder (Kyaga et al., 2013).

Actor Russell Brand

Writer Virginia Woolf

Humorist Samuel Clemens (Mark Twain)

Left: Dave Bedrosian/ZUMA Press/Newscom; Center: George C. Beresford/Getty Images; Right: The Granger Collection, NYC—All Rights Reserved.

Creativity and bipolar disorder There have been many creative artists, composers, writers, and musical performers with bipolar disorder.

Though bipolar disorder is much less common than major depressive disorder, it is often more dysfunctional, claiming twice as many lost workdays yearly (Kessler et al., 2006). It is also a potent predictor of suicide (Schaffer et al., 2015). Unlike major depressive disorder, bipolar disorder afflicts as many men as women. The diagnosis has risen among adolescents, whose mood swings, sometimes prolonged, may vary from raging to bubbly. In the decade between 1994 and 2003, bipolar diagnoses in Americans under the age of 20 revealed an astonishing 40-fold increase—from an estimated 20,000 to 800,000 (Carey, 2007; Flora & Bobby, 2008; Moreno et al., 2007). Americans are twice as likely as people of other countries to have ever had a diagnosis of bipolar disorder (Merikangas et al., 2011). The new DSM-5 classifications have, however, begun to reduce the number of child and adolescent bipolar diagnoses: Some of those who are persistently irritable and who have frequent and recurring behavior outbursts are now instead diagnosed with *disruptive mood dysregulation disorder* (Faheem et al., 2017).

Understanding Depressive Disorders and Bipolar Disorder

67-2 How can the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorder?

Terry Gatanis/ZUMA Press/Newscom

Life after depression J. K. Rowling, author of the Harry Potter books, reported suffering acute depression—a "dark time," with suicidal thoughts—between ages 25 and 28. It was a "terrible place," she said, but it formed a foundation that allowed her "to come back stronger" (McLaughlin, 2010).

Today's psychologists continue to sleuth why people have depressive disorders and bipolar disorder, and to design more effective ways to treat and prevent them. Here, we focus primarily on depressive disorders. One research group summarized the facts that any theory of depression must explain, including the following (Lewinsohn et al., 1985, 1998, 2003):

- ***Behavioral and cognitive changes accompany depression.*** People trapped in a depressed mood become inactive and feel alone, empty, and without a bright or meaningful future (Bullock & Murray, 2014; Khazanov & Ruscio, 2016; Smith & Rhodes, 2014). They avoid positive information and attend selectively to negative events (Peckham et al., 2010; Winer & Salem, 2016). They more often recall negative information. They expect negative outcomes (my team will lose, my grades will fall, my love will fail). When the depression lifts, these behavioral and cognitive accompaniments disappear. Nearly half the time, people also exhibit symptoms of another disorder, such as anxiety or substance abuse.

- ***Depression is widespread.*** Worldwide, 350 million people have major depressive disorder and 60 million people have bipolar disorder (WHO, 2017a). At some point during their lifetime, depression has plagued 11 percent of Canadian 15- to 24-year-olds (Findlay, 2017). Depression's commonality suggests that its causes, too, must be common.
- ***Women's risk of major depressive disorder is nearly double men's.*** In 2009, when Gallup pollsters asked more than a quarter-million Americans if they had ever been diagnosed with depression, 13 percent of men and 22 percent of women said they had (Pelham, 2009). When Gallup asked Americans if they had experienced sadness "during a lot of the day yesterday," 17 percent of men and 28 percent of women answered *Yes* (Mendes & McGeeney, 2012). The depression gender gap —with U.S. women experiencing depression 1.7 times more often than men (CDC, 2014a)—has been found worldwide (**Figure 67.1**). The trend begins in adolescence; preadolescent girls are not more depression-prone than are boys (Kuehner, 2017). After reaching puberty, girls also become more vulnerable than boys to eating disorders, self-injury, and anxiety (Mendle et al., 2016). Menopause—more specifically, "the 5 or 6 years surrounding the last menstrual period"—is also a time of women's increased depression risk, though in later life, the depression gender gap diminishes (Gordon et al., 2016; Patten et al., 2016).

  The factors that put women at risk for depression (genetic predispositions, child abuse, low self-esteem, marital problems, and so forth) similarly put men at risk (Kendler et al., 2006). Yet women are more vulnerable to disorders involving internalized states such as depression, anxiety, and inhibited sexual desire. Women experience more situations that increase their risk for depression, such as receiving less pay for equal work, juggling multiple roles, and caring for children and elderly family members (Freeman & Freeman, 2013). Men’s disorders tend to be more external—alcohol use disorder, and disorders related to antisocial conduct and lack of impulse control. When women get sad, they often get sadder than men do. When men get mad, they often get madder than women do.

- ***Most major depressive episodes self-terminate.*** Therapy often helps and tends to speed recovery. But even without professional help, most people recover from depression and return to normal. The plague of depression comes and, a few weeks or months later, it goes, though for some (about half), it eventually returns (Curry et al., 2011; Klein & Kotov, 2016). Only about 20 percent experience chronic depression (Klein, 2010). On average, a person with major depressive disorder today will spend about three-fourths of the next decade in a normal, nondepressed state (Furukawa et al., 2009). In one study of over 20,000 Canadians, an enduring recovery was more likely if the first episode struck later in life, there was no prior history of depression, people experienced minimal physical or psychological stress, and they had ample social support (Fuller-Thomson et al., 2016).
- ***Stressful events related to work, marriage, and close relationships often precede depression.*** As anxiety is a response to the threat of future loss, depression is often a response to past and current stress. Experiencing childhood abuse doubles a person’s risk of adult depression (Nelson et al., 2017). About 1 person in 4 diagnosed with depression has been brought down by a significant loss or trauma, such as a loved one’s death, a ruptured marriage, a physical assault, or a lost job (Kendler et al., 2008; Monroe & Reid, 2009; Orth et al., 2009; Wakefield et al., 2007). Moving to a new culture also increases risk for depression, especially among younger people who have not yet formed their identities (Zhang et al., 2013). One long-term study (Kendler, 1998) tracked rates of depression in 2000 people. The risk of depression ranged from less than 1 percent among those who had experienced no stressful life event in the preceding month to 24 percent among those who had experienced three such events in that month. For some,

grappling with life’s minor daily stressors can also negatively impact mental health. People who overreacted to minor stressors, such as a broken appliance, were more often depressed 10 years later (Charles et al., 2013).

- ***Compared to generations past, depression strikes earlier (now often in the late teens) and affects more people, with the highest rates among young adults in developed countries.*** Although adolescent depression rates have recently leveled off, this trend has been reported in Canada, the United States, England, France, Germany, Italy, Lebanon, New Zealand, Puerto Rico, and Taiwan (Cross-National Collaborative Group, 1992; Kessler et al., 2010; Olfson et al., 2015). In one study, 12 percent of Australian adolescents reported symptoms of depression (Sawyer et al., 2000). Most hid it from their parents, almost 90 percent of whom perceived their depressed teen as *not* suffering depression. In North America, young adults are three times more likely than their grandparents to report having recently—or ever—suffered depression (despite the grandparents’ many more years of being at risk). The increase may reflect a cultural difference of today’s young adults’ greater willingness to disclose depression.

Figure 67.1 Gender and major depressive disorder

Interviews with 89,037 adults in 18 countries (10 of which are shown here) confirm what many smaller studies have found: Women’s risk of major depressive disorder is nearly double men’s.

Armed with these facts, today’s researchers propose biological and cognitive explanations of depression, often combined in a biopsychosocial perspective.

The Biological Perspective

Depression is a whole-body disorder. It involves genetic predispositions and biochemical imbalances, as well as negative thoughts and a gloomy mood.

Genetic Influences

Depressive disorders and bipolar disorder run in families. As one researcher noted, emotions are “postcards from our genes” (Plotkin, 1994). The risk of being diagnosed with one of these disorders increases if your parent or sibling has the disorder (Sullivan et al., 2000; Weissman et al., 2016). If one identical twin is diagnosed with major depressive disorder, the chances are about 1 in 2 that at some time the other twin will be, too. If one identical twin has bipolar disorder, the chances of a similar diagnosis for the co-twin are even higher—7 in 10—even for twins raised apart (DiLalla et al., 1996). Summarizing the major twin studies, one research team estimated the heritability of major depressive disorder—the extent to which individual differences are attributable to genes—at 40 percent (Polderman et al., 2015; see also **Figure 67.2** for another study’s similar heritability findings for this and other disorders).

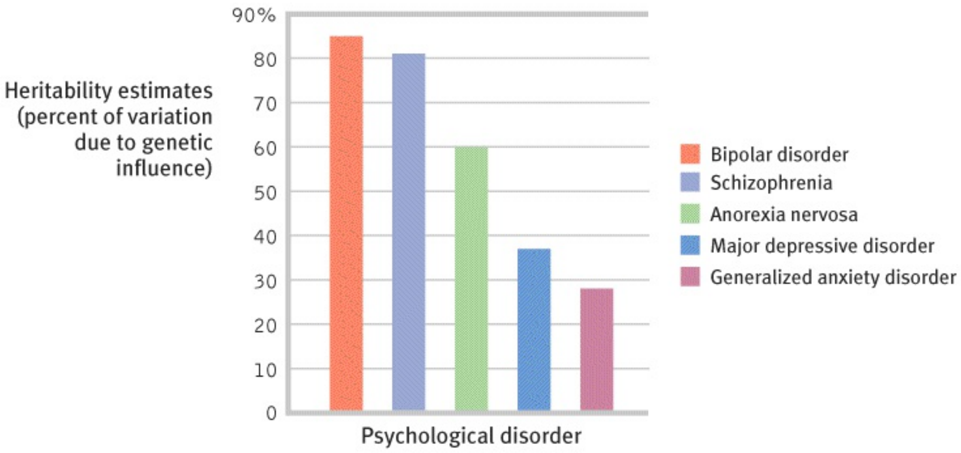

Figure 67.2

Myers/DeWall, *Myers’ Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 67.2 The heritability of various psychological disorders

Using aggregated data from studies of identical and fraternal twins, researchers estimated the heritability of bipolar disorder, schizophrenia, anorexia nervosa, major depressive disorder, and generalized anxiety disorder (Bienvenu et al., 2011). (Heritability was calculated by a formula that compares the extent of similarity among identical versus fraternal twins.)

To tease out the genes that put people at risk for depression, some researchers have turned to *linkage analysis*. First, geneticists find families in which the disorder appears across several generations. Next, the researchers examine DNA from affected and unaffected family members, looking for differences. Linkage analysis points them to a chromosome neighborhood; "A house-to-house search is then needed to find the culprit gene" (Plomin & McGuffin, 2003). But depression is a complex condition. Many genes work together, producing a mosaic of small effects that interact with other factors to put some people at greater risk. Researchers continue to identify culprit gene variations that may open the door to more effective drug therapy (Hyde et al., 2016; Power et al., 2017).

The Depressed Brain

Scanning devices let us eavesdrop on the brain's activity during depressed and manic states. One study gave 13 elite Canadian swimmers the wrenching experience of watching a video of the swim in which they failed to make the Olympic team or failed at the Olympic games (Davis et al., 2008). Functional MRI scans showed the disappointed swimmers experiencing brain activity patterns similar to those of people with depressed moods.

Many studies have found diminished brain activity during slowed-down depressive states, and more activity during periods of mania (**Figure 67.3**). Depression can cause the brain's reward centers to become less active (Miller et al., 2015; Stringaris et al., 2015). During positive emotions, the left frontal lobe and an adjacent reward center become more active (Davidson et al., 2002; Robinson et al., 2012).

Figure 67.3 The ups and downs of bipolar disorder

These top-facing PET scans show that brain energy consumption rises and falls with the patient's emotional switches. Red areas are where the brain rapidly consumes glucose.

Neuroscientists have also discovered altered brain structures in people with bipolar disorder. These studies discovered a decrease in myelinated axons (see Module 9) and enlarged fluid-filled ventricles (Arnone et al., 2009; Hibar et al., 2016).

Neurotransmitter systems also influence depressive disorders and bipolar disorder. *Norepinephrine*, which increases arousal and boosts mood, is scarce during depression and overabundant during mania. Drugs that decrease mania reduce norepinephrine.

Serotonin is also scarce or inactive during depression (Carver et al., 2008). One well-publicized study of New Zealand young adults found that the recipe for depression combined two necessary ingredients—significant life stress plus a variation of a serotonin-controlling gene (Caspi et al., 2003; Moffitt et al., 2006). Depression arose from the combination of an adverse environment plus a genetic susceptibility, but not from either alone. But stay tuned: The story of gene-environment interactions is still being written, as other researchers debate the reliability of this result (Culverhouse et al., 2013; Karg et al., 2011).

AP® EXAM TIP

This is a good time to review Unit III. Consider how the use of brain scans (such as the MRI and PET) and knowledge about neurotransmitters (such as norepinephrine and serotonin) have helped us understand depression and mania.

Drugs that relieve depression tend to increase norepinephrine or serotonin supplies by blocking either their reuptake (as Prozac, Zoloft, and Paxil do with serotonin) or their chemical breakdown. Repetitive physical exercise, such as jogging, reduces depression in part because it increases serotonin, which affects mood and arousal (Airan et al., 2007; Ilardi, 2009; Jacobs, 1994). In one study, running for two hours increased brain activation in regions associated with euphoria (Boecker et al., 2008). To run away from a bad mood, you can use your own two feet.

Nutritional Effects

What's good for the heart is also good for the brain and mind. People who eat a heart-healthy "Mediterranean diet" (heavy on vegetables, fish, and olive oil) have a comparatively low risk of developing heart disease, stroke, late-life cognitive decline, and depression—all of which are associated with inflammation (Kaplan et al., 2015; Psaltopoulou et al., 2013; Rechenberg, 2016). Excessive alcohol use also correlates with depression, partly because depression can increase alcohol use but mostly because alcohol misuse *leads* to depression (Fergusson et al., 2009).

FYI

Microbes and the mind: Digestive system bacteria produce neurotransmitters that influence human emotions and social interactions (Dinan et al., 2015; Kaplan et al., 2015; Nowakowski et al., 2016).

The Social-Cognitive Perspective

Biological influences contribute to depression, but in the nature–nurture dance, our life experiences also play a part. Diet, drugs, stress, and other environmental influences lay down *epigenetic marks*, molecular genetic tags that can turn certain genes on or off. Animal studies suggest that long-lasting epigenetic influences may play a role in depression (Nestler, 2011).

Thinking matters, too. The *social-cognitive perspective* explores how people's assumptions and expectations influence what they perceive. Many depressed people view life through the dark glasses of low self-esteem (Orth et al., 2016). Their intensely negative assumptions about themselves, their situation, and their future lead them to magnify bad experiences and minimize good ones (Wenze et al., 2012). Listen to Norman, a Canadian university professor, recalling his depression:

> I [despaired] of ever being human again. I honestly felt subhuman, lower than the lowest vermin. Furthermore, I was self-deprecatory and could not understand why anyone would want to associate with me, let alone love me. . . . I was positive that I was a fraud and a phony and that I didn't deserve my Ph.D. . . . I didn't deserve the research grants I had been awarded; I couldn't understand how I had written books and journal articles. . . . I must have conned a lot of people. (Endler, 1982, pp. 45–49)

Expecting the worst, depressed people's *self-defeating beliefs* and their *negative explanatory style* feed their depression.

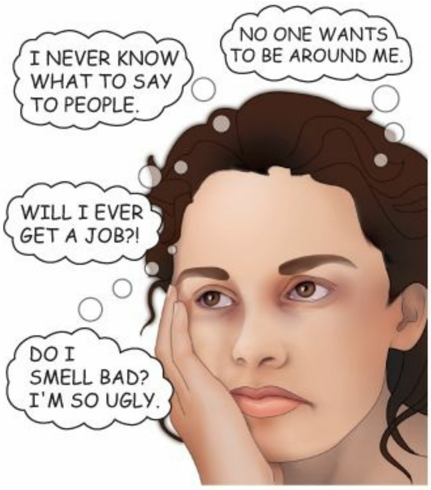
Negative Thoughts, Negative Moods, and Gender

Women may respond more strongly to stress (Hankin & Abramson, 2001; Mazure et al., 2002; Nolen-Hoeksema, 2001, 2003). For example, 38 percent of women and 17 percent of men entering American colleges and universities have reported feeling at least occasionally "overwhelmed by all I have to do" (Pryor et al., 2006). Relationship stresses also affect teen girls more than boys (Hamilton et al., 2015).

This gender stress difference may help explain why, beginning in their early teens, women have been nearly twice as vulnerable to depression. Susan Nolen-Hoeksema (2003) related women's higher risk of depression to what she described as their tendency to ruminate or *overthink*. Staying focused on a problem (thanks to the continuous firing of a frontal lobe area that sustains attention)—can be adaptive (Altamirano et al., 2010; Andrews & Thomson, 2009a,b). But relentless, self-focused **rumination** can distract us, increase negative emotion, and disrupt daily activities (Johnson et al., 2016; Kircanski et al., 2015; Yang et al., 2017). Comparisons can also feed misery. While Josh is happily playing video games, lonely Lauren scrolls through her social media feed and sees Maria having a blast with friends, Angelique enjoying a family vacation, and Tyra looking super in a swimsuit. In response, Lauren broods: “My life is terrible.”

rumination

compulsive fretting; *overthinking* our problems and their causes.



I NEVER KNOW WHAT TO SAY TO PEOPLE.
NO ONE WANTS TO BE AROUND ME.
WILL I EVER GET A JOB?!
DO I SMELL BAD? I'M SO UGLY.

Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

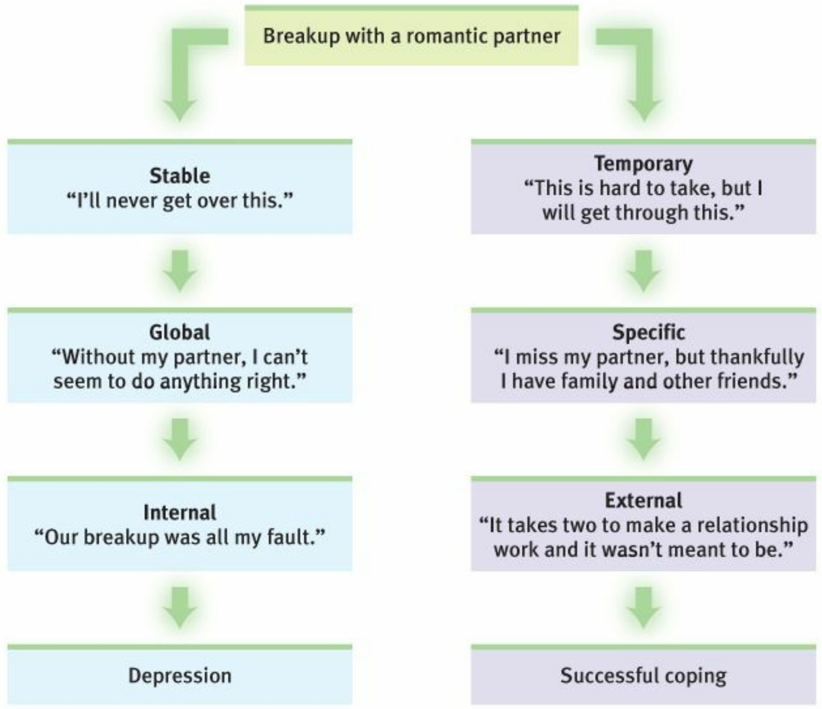
Rumination runs wild It’s normal to think about our flaws. But dwelling constantly on negative thoughts—particularly negative thoughts about ourselves—makes it difficult to believe in ourselves and solve problems. People sometimes seek therapy to reduce their rumination.

Even so, why do life’s unavoidable failures lead only some people to become depressed? The answer lies partly in their *explanatory style*—who or what they blame for their failures. Think of how you might feel if you failed a test. If you can externalize the blame (“What an unfair test!”), you are more likely to feel angry. If you blame yourself, you probably will feel stupid and depressed.

> “ *I think I, like a lot of people, have that type of brain where I find it interesting or*

> *fulfilling to worry about something.*”
>
> *Comedian Maria Bamford*

So it is with depressed people, who often explain bad events in terms that are *stable* (“It’s going to last forever”), *global* (“It’s going to affect everything I do”), and *internal* (“It’s all my fault”) (**Figure 67.4**). Depression-prone people respond to bad events in an especially self-focused, self-blaming way (Huang, 2015; Mor & Winquist, 2002; Wood et al., 1990a,b). When they describe themselves, their brains show extra activity in a region that processes self-relevant information (Sarsam et al., 2013). Their self-esteem is also more plastic—it climbs with praise and plummets with threats (Butler et al., 1994).



Breakup with a romantic partner
Stable
“I’ll never get over this.”
Temporary
“This is hard to take, but I will get through this.”
Global
“Without my partner, I can’t seem to do anything right.”
Specific
“I miss my partner, but thankfully I have family and other friends.”
Internal
“Our breakup was all my fault.”
External
“It takes two to make a relationship work and it wasn’t meant to be.”
Depression
Successful coping

Figure 67.4 Explanatory style and depression

After a difficult experience, a depression-prone person may respond with a negative explanatory style.

Self-defeating beliefs may arise from *learned helplessness*, the hopelessness and passive resignation humans and other animals learn when they experience uncontrollable painful events (Maier & Seligman, 2016) (see Module 29). Pessimistic, overgeneralized, self-blaming attributions may create a depressing sense of hopelessness (Abramson et al., 1989; Panzarella et al., 2006). As Martin Seligman has noted, “A recipe for severe depression is preexisting pessimism encountering failure” (1991, p. 78). What then might we expect of new college students who exhibit a pessimistic explanatory style? Lauren Alloy and her colleagues (1999) monitored several hundred students every 6 weeks for 2.5 years. Among those identified as having a pessimistic thinking style, 17 percent had a first episode of major depression, as did only 1 percent of those who began college with an optimistic thinking style.

Why is depression so common among young Westerners? Seligman (1991, 1995) pointed to the rise of individualism and the decline of commitment to religion and family. In non-Western cultures, where close-knit relationships and cooperation are the norm, major depressive disorder is less common and less tied to self-blame over personal failure (Ferrari et al., 2013; WHO, 2004a). In Japan, for example, depressed people instead tend to report feeling shame over letting others down (Draguns, 1990a).

Critics note a chicken-and-egg problem nesting in the social-cognitive explanation of depression. Which comes first—the pessimistic explanatory style or the depressed mood? The negative explanations *coincide* with a depressed mood, and they are *indicators* of depression. (Before or after being depressed, people’s thoughts are less negative. Perhaps a depressed mood triggers negative thoughts.) But do negative thoughts *cause* depression, any more than a speedometer’s reading *causes* a car’s speed? If you temporarily put people in a bad or sad mood, their memories, judgments, and expectations suddenly become more pessimistic. Memory researchers call this tendency to recall experiences that fit our current good or bad mood *state-dependent memory* (Module 32).

“You should never engage in unsupervised introspection.”

Depression’s Vicious Cycle

Depression is both a cause and an effect of stressful experiences that disrupt our sense of who we are and why we are worthy human beings. Such disruptions can lead to brooding, which amplifies negative feelings. Being withdrawn, self-focused, and complaining can in turn elicit rejection (Furr & Funder, 1998; Gotlib & Hammen, 1992). Indeed, people in the throes of depression are at high risk for divorce, job loss, and other stressful life events. Weary of the person’s fatigue, hopeless attitude, and negativity, a spouse may threaten to leave or a boss may begin to question the person’s competence. (This provides another example of genetic-environmental interaction: People genetically predisposed to depression more often experience depressing events.) Rejection and depression feed each other. Misery may love another’s company, but company does not love another’s misery.

> “*Man never reasons so much and becomes so introspective as when he suffers, since he is anxious to get at the cause of his sufferings.*”
>
> *Luigi Pirandello,* Six Characters in Search of an Author, *1922*

We can now assemble some of the pieces of the depression puzzle (**Figure 67.5**): (1) Stressful experiences interpreted through (2) a ruminating, pessimistic explanatory style create (3) a hopeless, depressed state that (4) hampers the way the person thinks and acts. This, in turn, fuels (1) further stressful experiences such as rejection. Depression is a snake that bites its own tail.

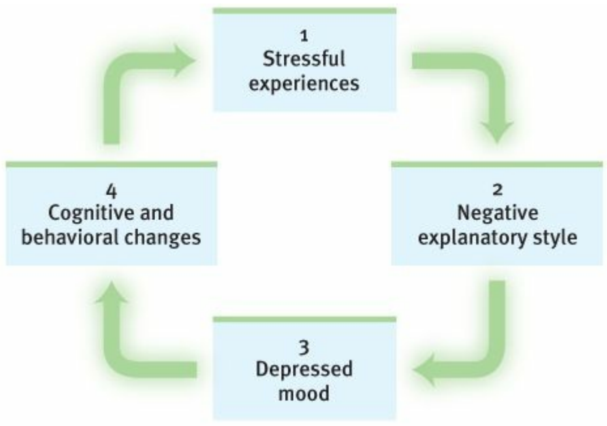

Figure 67.5
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 67.5 The vicious cycle of depressed thinking

Therapists recognize this cycle, and they work to help depressed people break out of it by changing their negative thinking, turning their attention outward, and engaging them in more pleasant and competent behavior.

None of us are immune to the dejection, diminished self-esteem, and negative thinking brought on by rejection or defeat. Even small losses can temporarily sour our thinking. In one study, researchers studied some avid Indiana University basketball fans who seemed to regard the team as an extension of themselves (Hirt et al., 1992). After the fans watched their team lose or win, the researchers asked them to predict the team's future performance and their own. After a loss, the morose fans offered bleaker assessments not only of the team's future but also of their own likely performance at throwing darts, solving anagrams, and getting a date. When things aren't going our way, it may seem as though they never will.

> “*Some cause happiness wherever they go; others, whenever they go.*”
>
> *Irish writer Oscar Wilde (1854–1900)*

It is a cycle we can all recognize. Bad moods feed on themselves: When we feel down, we think negatively and remember bad experiences. Britain's Prime Minister Winston Churchill called depression a "black dog" that periodically hounded him. Abraham Lincoln was so withdrawn and brooding as a young man that his friends feared he might take his own life (Kline, 1974). Poet Emily Dickinson was so afraid of bursting into tears in public that she spent much of her adult life in seclusion (Patterson, 1951). As their lives remind us, people can and do struggle through depression. Most regain their capacity to love, to work, and even to succeed at the highest levels.

Suicide and Self-Injury

67-3 What factors increase the risk of suicide, and what do we know about nonsuicidal self-injury?

Each year over 800,000 despairing people worldwide will elect a permanent solution to what might have been a temporary problem (WHO, 2014b). For those who have been anxious, the risk of suicide is tripled, and for those who have been depressed, the risk is quintupled (Bostwick & Pankratz, 2000; Kanwar et al., 2013). People seldom commit suicide while in the depths of depression, when energy and initiative are lacking. The risk increases when they begin to rebound and become capable of following through (Chu et al., 2016).

Comparing the suicide rates of different groups, researchers have found

- ***national differences:*** In Britain, Italy, and Spain, suicide rates have been little more than half those of Canada, Australia, and the United States. Austria's and Finland's are about double (WHO, 2011). Within Europe, people in the most suicide-prone country (Belarus) have been 16 times more likely to kill themselves than those in the least (Georgia).
- ***racial differences:*** Within the United States, Whites and Native Americans kill themselves twice as often as Blacks, Hispanics, and Asians (CDC, 2012).
- ***gender differences:*** Women are much more likely than men to *attempt* suicide (WHO, 2011). But men are two to four times more likely (depending on the country) to actually end their lives. Men use more lethal methods, such as firing a bullet into the head, the method of choice in 6 of 10 U.S. suicides.
- ***age differences:*** In late adulthood, rates increase, with the highest rate among 45- to 64-year-olds and the second-highest among those 85 and older (AFSP, 2015).
- ***other group differences:*** Suicide rates have been much higher among

the rich, the nonreligious, and those single, widowed, or divorced (Hoyer & Lund, 1993; Norko et al., 2017; Okada & Samreth, 2013; VanderWeele et al., 2016, 2017). Witnessing physical pain and trauma can increase the risk of suicide, which may help explain veterans' and physicians' elevated suicide rates (Bender et al., 2012; Cornette et al., 2009). Gay, transgender, and gender nonconforming youth facing an unsupportive environment, including family or peer rejection, are also at increased risk of attempting suicide (Goldfried, 2001; Haas et al., 2011; Hatzenbuehler, 2011; Testa et al., 2017). Among people with alcohol use disorder, 3 percent die by suicide. This rate is roughly 100 times greater than the rate for people without alcohol use disorder (Murphy & Wetzel, 1990; Sher, 2006).

- ***day of the week and seasonal differences:*** Negative emotion tends to go up midweek, which can have tragic consequences (Watson, 2000). A surprising 25 percent of U.S. suicides occur on Wednesdays (Kposowa & D'Auria, 2009). Suicide rates are highest in April and May, and not (as commonly believed) over the winter holidays (Nock, 2016).

Social suggestion may trigger suicide. Following highly publicized suicides and TV programs featuring suicide, known suicides increase. So do fatal auto and private airplane "accidents." One six-year study tracked suicide cases among all 1.2 million people who lived in metropolitan Stockholm at any time during the 1990s (Hedström et al., 2008). Men exposed to a family suicide were 8 times more likely to commit suicide than were nonexposed men. That phenomenon may be partly attributable to family genes. But shared genetic predispositions cannot explain why men exposed to a co-worker's suicide were 3.5 times more likely to commit suicide compared with nonexposed men.

Suicide is not necessarily an act of hostility or revenge. People—especially older adults—may choose death as an alternative to current or future suffering, a way to switch off unendurable pain and relieve a perceived burden on family members. Suicidal urges typically arise when people feel disconnected from others and a burden to them, or when they feel defeated and trapped by an inescapable situation (Joiner, 2010; Taylor et al., 2011). Thus, suicide rates increase with unemployment during economic recessions (DeFina & Hannon, 2015; Reeves et al., 2014). Suicidal thoughts also may increase when people are driven to reach a goal or standard—to become thin or straight or rich—and find it unattainable (Chatard & Selimbegovic´, 2011).

In hindsight, families and friends may recall signs they believe should have forewarned them—verbal hints, giving possessions away, or withdrawal and preoccupation with death. To judge from surveys of 84,850 people across 17 nations, about 9 percent of people at some point in their lives have thought seriously of suicide. About 3 in 10 of those who think about it will actually attempt suicide (Nock et al., 2008). Only 3 percent of Americans die in that attempt (Han et al., 2016). In one study that followed people for up to 25 years after a first suicide attempt, some 5 percent died by suicide (Bostwick et al., 2016). One group of clinical psychologists summarized 50 years of research on suicide’s unpredictability: “The vast majority of people who possess a specific risk factor [for suicide] will never engage in suicidal behavior” (Franklin et al., 2017, p. 217).

But researchers continue to try to solve the suicide puzzle. Although most suicide attempts fail, the risk of death by suicide is seven times greater among those who have previously attempted suicide (Al-Sayegh et al., 2015). Each year, about 40,000 Americans will kill themselves—about two-thirds using guns. (Drug overdoses account for about 80 percent of suicide attempts, but only 14 percent of suicide fatalities.) States with high gun ownership are states with high suicide rates, even after controlling for poverty and urbanization (Miller et al., 2002, 2016; Tavernise, 2013). After Missouri repealed its tough handgun law, its suicide rate went up 15 percent; when Connecticut enacted such a law, its suicide rate dropped 16 percent (Crifasi et al., 2015). Thus, although U.S. gun owners often keep a gun to feel safer, having a gun in the home makes one less safe, because it substantially *increases* the odds of a family member dying by suicide or homicide (Kposowa et al., 2016; VPC, 2015; Vyse, 2016).

FYI

Does a full moon trigger “madness” in some people? James Rotton and I. W. Kelly (1985) examined data from 37 studies that related lunar phase to crime, homicides, crisis calls, and psychiatric hospital admissions. Their conclusion: There is virtually no evidence of “moon madness.” Nor does lunar phase correlate with suicides, assaults, emergency room visits, or traffic disasters (Martin et al., 1992; Raison et al., 1999).

How can we be helpful to someone who is talking suicide—who says, for example, “I wish I could just end it all” or “I hate my life; I can’t go on”? If people write such things online, you can anonymously contact the safety teams at various social media websites (including Facebook, Twitter, Instagram, YouTube, and Tumblr). If a friend or family member talks suicide, you can

1. listen and empathize;
2. *connect* the person with your school psychologist or counselor, with (in the United States) the Suicide Prevention Lifeline (1-800-273-TALK) or Crisis Text Line (by texting HOME to 741741), or with their counterparts in other countries (such as the LifeLine App in Canada); and
3. *protect* someone who appears at risk by seeking help from a trusted adult—a parent, a teacher, a school nurse or school counselor—or calling 911. Better to share a secret than to attend a funeral.

> “ *People desire death when two fundamental needs are frustrated to the point of extinction: The need to belong with or connect to others, and the need to feel effective with or to influence others.* ”
>
> *Thomas Joiner (2006, p. 47)*

Nonsuicidal Self-Injury

Self-harm takes many forms. Some people may engage in *nonsuicidal self-injury (NSSI)*, which is more common in adolescence and among females (CDC, 2009) (**Figure 67.6**). Such behavior, though painful, is not fatal. Those who engage in NSSI may cut or burn their skin, hit themselves, insert objects under their nails or skin, or self-administer tattoos. People who engage in NSSI tend to experience bullying, harassment, and other life stress (Liu et al., 2016; van Geel et al., 2015). They are generally less able to tolerate and regulate emotional distress (Hamza et al., 2015). They are often extremely self-critical and struggle to communicate, solve problems, and perform academically (Kiekens et al., 2016; Nock, 2010; You et al., 2015). Why do they hurt themselves? Reinforcement processes are at work (Bentley et al., 2014). Through NSSI they may

- find relief from intense negative thoughts through the distraction of pain.
- attract attention and possibly get help.
- relieve guilt by punishing themselves.
- get others to change their negative behavior (bullying, criticism).
- fit in with a peer group.

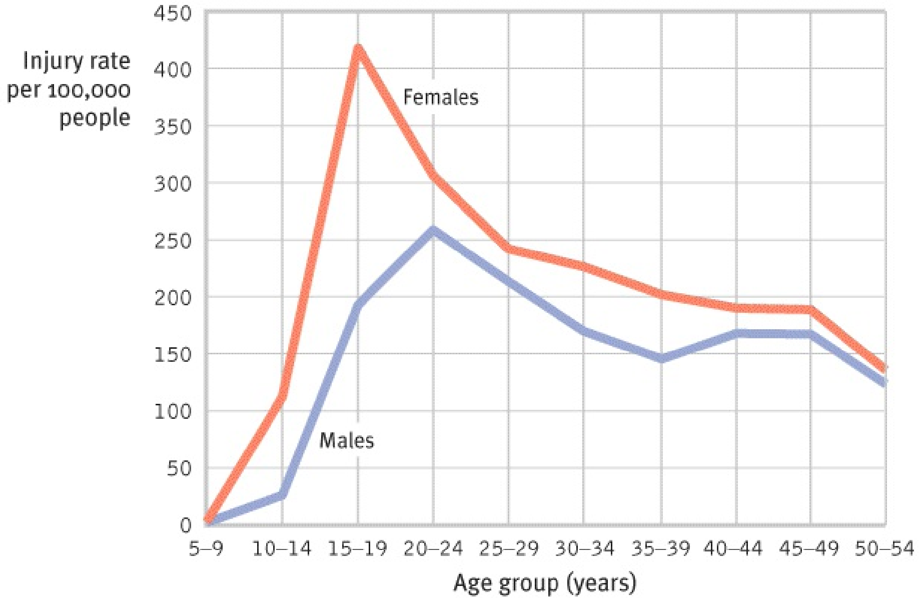

Figure 67.6
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from CDC, 2009.

Figure 67.6 Rates of nonfatal self-injury in the United States

Self-injury rates peak higher for females than for males.

Does NSSI lead to suicide? Usually not. Those who engage in NSSI are typically suicide gesturers, not suicide attempters (Nock & Kessler, 2006). Nevertheless, NSSI is a risk factor for suicidal thoughts and future suicide attempts, especially when coexisting with bipolar disorder (Hawton et al., 2015; Runeson et al., 2016; Willoughby et al., 2015). If people do not find help, their nonsuicidal behavior may escalate to suicidal thoughts and, finally, to suicide attempts.

✓ Check Your Understanding

Ask Yourself

- Has your high school experience been a challenging time for you? What advice would you have for other students about to enter high school?

Test Yourself

- What does it mean to say that “depression is a whole-body disorder”?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 67 REVIEW

67-1 How do major depressive disorder, persistent depressive disorder, and bipolar disorder differ?

- A person with *major depressive disorder* experiences at least five symptoms of depression (including either depressed mood or loss of interest or pleasure) for two or more weeks.
- A person with persistent depressive disorder experiences a mildly depressed mood more often than not for at least two years, as well as at least two symptoms of depression.
- A person with the less common condition of *bipolar disorder* experiences not only depression but also *mania*—episodes of hyperactive and wildly optimistic, impulsive behavior.

67-2 How can the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorder?

- The biological perspective on depression focuses on genetic predispositions and on abnormalities in brain structures and function (including those found in neurotransmitter systems).
- The social-cognitive perspective views depression as an ongoing cycle of stressful experiences (interpreted through negative beliefs, attributions, and memories, and intensified by *rumination*) leading to negative moods and actions and fueling new stressful experiences.
- Both biology and environment contribute to epigenetic effects, which may play a role in depression.

67-3 What factors increase the risk of suicide, and what do we know about nonsuicidal self-injury?

- Suicide rates differ by nation, race, gender, age group, income, religious involvement, marital status, and other factors. Gay, transgender, and gender nonconforming youth lacking social support are at increased risk, as are people who have been anxious or depressed.

- Day of the week, season, or social suggestion may play a role in suicide risk.
- Personal trauma, disconnection, or defeat can contribute to suicidal urges.
- Forewarnings of suicide may include verbal hints, giving away possessions, withdrawal, preoccupation with death, and discussing one's own suicide.
- Nonsuicidal self-injury (NSSI) does not usually lead to suicide but may escalate to suicidal thoughts and acts if untreated.
- People who engage in NSSI do not tolerate stress well and tend to be self-critical, with poor communication and problem-solving skills.

Multiple-Choice Questions

1. After spending several weeks barely able to get out of bed, Hatch finds himself with so much energy that he surprises his wife by painting the entire house in one day. Concerned, his wife brings him to the hospital, where the doctors diagnose him with

a. suicidal thoughts.
b. bipolar disorder.
c. persistent depressive disorder.
d. rumination.
e. major depressive disorder.

2. Which of the following is true of depression?

a. Depression usually develops during middle age.
b. Depression usually happens without major cognitive or behavioral changes.
c. A major depressive episode usually gets worse and worse unless it's treated.

d. True depression is usually not related to stress in one’s work or relationships.
e. Compared with men, nearly twice as many women have been diagnosed with depression.

3. Concerning suicide,

a. marijuana use is related to suicide, but alcohol use is not.
b. women are more likely to attempt suicide than men.
c. suicide is a bigger problem among the poor than among the rich.
d. women are more likely to end their lives than men.
e. married individuals are more likely to commit suicide than single people.

4. Based on brain scans of those with bipolar disorder, which of the following is true?

a. The brain is more active during manic episodes and less active during depressive episodes.
b. The brain is less active during manic episodes and more active during depressive episodes.
c. There is no consistent relationship between brain activity and periods of mania or depression.
d. The brain is more active than normal during both manic and depressive episodes.
e. The brain is less active than normal during both manic and depressive episodes.

5. During depression, researchers have found

I. reduced levels of serotonin.
II. reduced levels of norepinephrine.
III. reduced activity in the hypothalamus.

a. I only.
b. II only.
c. III only.
d. I & II only.

e. I & III only.

Practice FRQs

1. Depression is often misunderstood as “sad” and mania is often misunderstood as “happy.” Provide two examples for each of these disordered behaviors that could help clarify this misunderstanding.

Answer

2 points: Depression examples could include any two behaviors that illustrate the following: a lack of interest in activities, feelings of hopelessness, reduced energy levels, problems with sleep, and problems with appetite. Page 687

2 points: Mania examples could include any two behaviors that illustrate the following: little need for sleep, wildly increased energy levels, dangerous risk-taking, and extreme optimism. Page 687

2. Marty was dumped by his girlfriend and has developed depression. Explain Marty’s thinking about his situation using the following terms:

- Learned helplessness
- Rumination

(2 points)

Module **68 Schizophrenia**

LEARNING TARGETS

- 68-1 Describe the patterns of perceiving, thinking, and feeling that characterize schizophrenia.
- 68-2 Contrast chronic schizophrenia and acute schizophrenia.
- 68-3 Discuss the brain abnormalities associated with schizophrenia.
- 68-4 Discuss the prenatal events associated with increased risk of developing schizophrenia.
- 68-5 Discuss how genes influence schizophrenia, and identify the factors that may be early warning signs of schizophrenia in children.

During their most severe periods, people with **schizophrenia** live in a private inner world, preoccupied with the strange ideas and images that haunt them. The word itself means “split” (*schizo*) “mind” (*phrenia*). It refers *not* to a multiple personality split but rather to the mind’s split from reality. People with schizophrenia have disturbed perceptions and beliefs, disorganized speech, and diminished, inappropriate emotions (and actions). Schizophrenia is the chief example of a **psychotic disorder**, a group of disorders marked by irrationality, distorted perceptions, and lost contact with reality.

schizophrenia

a disorder characterized by delusions, hallucinations, disorganized speech, and/or diminished, inappropriate emotional expression.

psychotic disorders

a group of disorders marked by irrational ideas, distorted perceptions, and a loss of contact with reality.

Symptoms of Schizophrenia

Flip It Video: Positive and Negative Symptoms of Schizophrenia

68-1 What patterns of perceiving, thinking, and feeling characterize schizophrenia?

Schizophrenia comes in varied forms. People with schizophrenia display symptoms that are *positive* (*inappropriate* behaviors are *present*) or negative (*appropriate* behaviors are *absent*). Those with *positive* symptoms may experience hallucinations, talk in disorganized and deluded ways, and exhibit inappropriate laughter, tears, or rage. Those with *negative* symptoms may exhibit an absence of emotion in their voices, expressionless faces, or unmoving—mute and rigid—bodies.

DISTURBED PERCEPTIONS AND BELIEFS People with schizophrenia sometimes have **hallucinations**—they see, feel, taste, or smell things that exist only in their minds. Most often, the hallucinations are voices, which sometimes make insulting remarks or give orders. The voices may tell the person that she is bad or that she must burn herself with a cigarette lighter. Imagine your own reaction if a dream broke into your waking consciousness, making it hard to separate your experience from your imagination. When the unreal seems real, the resulting perceptions are at best bizarre, at worst terrifying.

hallucinations

false sensory experiences, such as seeing something in the absence of an external visual stimulus.

Hallucinations are false *perceptions*. People with schizophrenia also have disorganized, fragmented thinking, often distorted by false *beliefs* called **delusions**. If they have *paranoid* tendencies, they may believe they are being threatened or pursued.

delusion

a false belief, often of persecution or grandeur, that may accompany psychotic disorders.

One cause of disorganized thinking may be a breakdown in *selective attention.* Recall from Module 16 that we normally we have a remarkable capacity to give our undivided attention to one set of sensory stimuli while filtering out others. People with schizophrenia are easily distracted by tiny unrelated stimuli, such as the grooves on a brick or tones in a voice. This selective attention difficulty is but one of dozens of cognitive differences associated with schizophrenia (Reichenberg & Harvey, 2007).

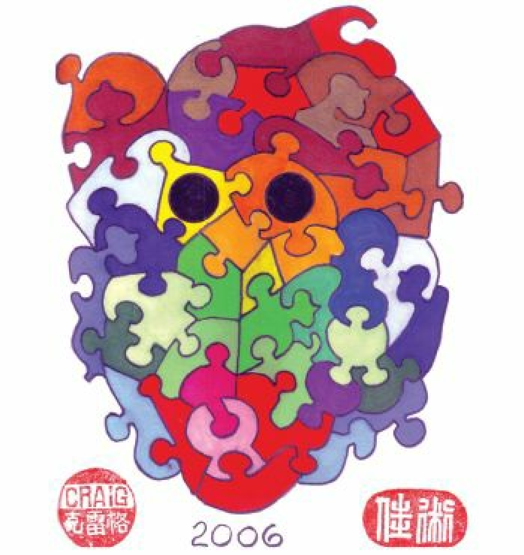
DISORGANIZED SPEECH Maxine, a young woman with schizophrenia, believed she was Mary Poppins. Communicating with Maxine was difficult because her thoughts spilled out in no logical order. Her biographer, Susan Sheehan (1982, p. 25), observed her saying aloud to no one in particular, “This morning, when I was at Hillside [Hospital], I was making a movie. I was surrounded by movie stars. . . . Is this room painted blue to get me upset? My grandmother died four weeks after my eighteenth birthday.”

Jumbled ideas may make no sense even within sentences, forming what is known as *word salad.* One young man begged for “a little more allegro in the treatment,” and suggested that “liberationary movement with a view to the widening of the horizon” will “ergo extort some wit in lectures.”

AP® EXAM TIP

When psychologists refer to “positive” and “negative” schizophrenia symptoms (as with positive and negative *reinforcement* in Unit VI), the terms *positive* and *negative* don’t mean “good” and “bad.” Symptoms are positive and negative in a mathematical sense (adding or subtracting behaviors).

DIMINISHED AND INAPPROPRIATE EMOTIONS The expressed emotions of schizophrenia are often utterly inappropriate, split off from reality (Kring & Caponigro, 2010). Maxine laughed after recalling her grandmother's death. On other occasions, she cried when others laughed, or became angry for no apparent reason. Others with schizophrenia lapse into an emotionless *flat affect* state of no apparent feeling. For example, monetary perks fail to provide the normal brain reward center activation (Radua et al., 2015). Most also have an *impaired theory of mind*—they have difficulty perceiving facial expressions and reading others' states of mind (Bora & Pantelis, 2016). Unable to understand others' mental states, those with schizophrenia struggle to feel sympathy and compassion (Bonfils et al., 2016). These emotional deficiencies occur early in the illness and have a genetic basis (Bora & Pantelis, 2013). Motor behavior may also be inappropriate and disruptive. Those with schizophrenia may experience *catatonia*, characterized by motor behaviors ranging from a physical stupor—remaining motionless for hours—to senseless, compulsive actions, such as continually rocking or rubbing an arm, to severe and dangerous agitation.



© Craig Geiser

Art by someone diagnosed with schizophrenia Commenting on the kind of artwork shown here (from Craig Geiser's 2010 art exhibit in Michigan), poet and art critic John Ashbery wrote: "The lure of the work is strong, but so is the terror of the unanswerable riddles it proposes."

AP® EXAM TIP

Be sure you can differentiate between hallucinations (false sensory experiences) and delusions (false beliefs).

As you can imagine, such disturbed perceptions and beliefs, disorganized speech, and out of place emotions profoundly disrupt social and work relationships. As with other disorders, many have sleep problems, which can increase night eating and obesity (Baglioni et al., 2016; Palmese et al., 2011). Given a supportive environment and medication, over 40 percent of people with schizophrenia will have periods of a year or more of normal life experience (Jobe & Harrow, 2010). But only 1 in 7 will have a full and enduring recovery (Jääskeläinen et al., 2013).

> “*Now consider this: The regulator that funnels certain information to you and filters out other information suddenly shuts off. Immediately, every sight, every sound, every smell coming at you carries equal weight; every thought, feeling, memory, and idea presents itself to you with an equally strong and demanding intensity.*”
>
> *Elyn R. Saks,* The Center Cannot Hold, *2007*

Onset and Development of Schizophrenia

68-2 How do chronic schizophrenia and acute schizophrenia differ?

This year, 1 in 100 people will join an estimated 21 million others worldwide who have schizophrenia (WHO, 2017a). This disorder knows no national boundaries, and it typically strikes as young people are maturing into adulthood. Men tend to be struck earlier, more severely, and more often (Aleman et al., 2003; Eranti et al., 2013; Picchioni & Murray, 2007).

When schizophrenia is a slow-developing process, called **chronic schizophrenia**, recovery is doubtful (Harrison et al., 2001; Jääskeläinen et al., 2013). This was the case with Maxine, whose schizophrenia took a slow course, emerging from a long history of social inadequacy and poor school performance (MacCabe et al., 2008). Social withdrawal, a negative symptom, is often found among those with chronic schizophrenia (Kirkpatrick et al., 2006). Men, whose schizophrenia develops on average four years earlier than women's, more often exhibit negative symptoms and chronic schizophrenia (Räsänen et al., 2000).

chronic schizophrenia

(also called *process schizophrenia*) a form of schizophrenia in which symptoms usually appear by late adolescence or early adulthood. As people age, psychotic episodes last longer and recovery periods shorten.

When previously well-adjusted people develop schizophrenia rapidly following particular life stresses, this is called **acute schizophrenia**, and recovery is much more likely. They more often have positive symptoms that respond to drug therapy (Fenton & McGlashan, 1991, 1994; Fowles, 1992).

acute schizophrenia

(also called *reactive schizophrenia*) a form of schizophrenia that can begin at any age; frequently occurs in response to a traumatic event.

Understanding Schizophrenia

Schizophrenia is one of the most heavily researched psychological disorders. Most studies now link it with abnormal brain tissue and genetic predispositions. Schizophrenia is a disease of the brain manifested in symptoms of the mind.

Brain Abnormalities

68-3 What brain abnormalities are associated with schizophrenia?

Might chemical imbalances in the brain underlie schizophrenia? Scientists have long known that strange behavior can have strange chemical causes. The saying "mad as a hatter" is often thought to refer to the psychological deterioration of British hat makers whose brains, it was later discovered, were slowly poisoned by the mercury-laden felt material (Smith, 1983). Could schizophrenia symptoms have a similar biochemical key? Scientists are searching for blood proteins that might predict schizophrenia onset (Chan et al., 2015). And as we saw in Module 25, they are tracking the mechanisms by which chemicals produce hallucinations and other symptoms.

Dopamine Overactivity

One possible answer emerged when researchers examined schizophrenia patients' brains after death. They found an excess number of *dopamine* receptors, including a sixfold excess for the dopamine receptor D4 (Seeman et al., 1993; Wong et al., 1986). Such a hyper-responsive dopamine system may intensify brain signals in schizophrenia, creating positive symptoms such as hallucinations and paranoia (Maia & Frank, 2017). Drugs that block dopamine receptors often lessen these symptoms. Drugs that increase dopamine levels, such as amphetamines and cocaine, sometimes intensify them (Basu & Basu, 2015; Farnia et al., 2014).

FYI

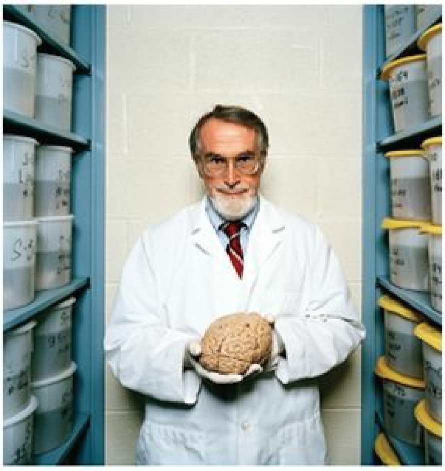
Most people with schizophrenia smoke. Smoking increases vulnerability to schizophrenia and contributes to people with schizophrenia having a 14.5-year shorter-than-average life expectancy (Gurillo et al., 2015; Hjorthøj et al., 2017; Olfson et al., 2015).

Abnormal Brain Activity and Anatomy

Abnormal brain activity and brain structures accompany schizophrenia. Some people diagnosed with schizophrenia have abnormally low brain activity in the frontal lobes, areas that help us reason, plan, and solve problems (Morey et al., 2005; Pettegrew et al., 1993; Resnick, 1992). Brain scans also show a noticeable decline in the brain waves that reflect synchronized neural firing in the frontal lobes (Spencer et al., 2004; Symond et al., 2005).

One study took PET scans of brain activity while people with schizophrenia were hallucinating (Silbersweig et al., 1995). When participants heard a voice or saw something, their brain became vigorously active in several core regions. One was the thalamus, the structure that filters incoming sensory signals and transmits them to the brain’s cortex. Another PET scan study of people with paranoia found increased activity in the amygdala, a fear-processing center (Epstein et al., 1998).

Many studies have also found enlarged, fluid-filled ventricles and a corresponding shrinkage and thinning of cerebral tissue (Goldman et al., 2009; van Haren et al., 2016). People often inherit these brain differences. If one affected identical twin shows brain abnormalities, the odds are at least 1 in 2 that the other twin’s brain will have them (van Haren et al., 2012). Some studies have even found these abnormalities in people who *later* developed the disorder (Karlsgodt et al., 2010). The greater the brain shrinkage, the more severe the thought disorder (Collinson et al., 2003; Nelson et al., 1998; Shenton, 1992).



© Chris Mueller/Redux Pictures

Studying the neurophysiology of schizophrenia Psychiatrist E. Fuller Torrey has collected the brains of hundreds of those who died as young adults and suffered disorders such as schizophrenia and bipolar disorder.

Smaller-than-normal areas may include the cortex, the hippocampus, and the corpus callosum connecting the brain's two hemispheres (Arnone et al., 2008; Bois et al., 2016). Another is the thalamus, which may explain why people with schizophrenia have difficulty filtering sensory input and focusing attention (Andreasen et al., 1994; Ellison-Wright et al., 2008). Schizophrenia also tends to involve a loss of neural connections across the brain network (Bohlken et al., 2016; Kambeitz et al., 2016). *The bottom line:* Schizophrenia involves not one isolated brain abnormality but problems with several brain regions and their interconnections (Andreasen, 1997, 2001; Arnedo et al., 2015).

Prenatal Environment and Risk

68-4 What prenatal events are associated with increased risk of developing schizophrenia?

What causes brain abnormalities in people with schizophrenia? Some scientists point to mishaps during prenatal development or delivery (Fatemi & Folsom, 2009; Walker et al., 2010). Risk factors include low birth weight, maternal diabetes, older paternal age, and oxygen deprivation during delivery (King et al., 2010). Famine may also increase risks. People conceived during the peak of World War II's Dutch wartime famine later developed schizophrenia at twice the normal rate. Those conceived during the famine of 1959 to 1961 in eastern China also displayed this doubled rate (St. Clair et al., 2005; Susser et al., 1996).

Let's consider another possible culprit. Might a midpregnancy viral infection impair fetal brain development (Brown & Patterson, 2011)? Can you imagine some ways to test this fetal-virus idea? Scientists have asked the following:

- *Are people at increased risk of schizophrenia if, during the middle of their fetal development, their country experienced a flu epidemic?* The repeated answer has been *Yes* (Mednick et al., 1994; Murray et al., 1992; Wright et al., 1995).
- *Are people born in densely populated areas, where viral diseases spread more readily, at greater risk for schizophrenia?* The answer, confirmed in a study of 1.75 million Danes, has again been *Yes* (Jablensky, 1999; Mortensen, 1999).
- *Are those born during the winter and spring months—those who were in utero during the fall-winter flu season—also at increased risk?* Although the increase is small, just 5 to 8 percent, the answer has been *Yes* (Fox, 2010; Schwartz, 2011; Torrey et al., 1997, 2002).
- *In the Southern Hemisphere, where the seasons are the reverse of the Northern Hemisphere, are the months of above-average pre-schizophrenia births similarly reversed?* Again, the answer has been *Yes*. In Australia, people born between August and October are at greater risk. But people born in the Northern Hemisphere who later moved to Australia still have a greater risk if they were born between January and March (McGrath et al., 1995; McGrath & Welham, 1999).
- *Are mothers who report being sick with influenza during pregnancy more likely to bear children who develop schizophrenia?* In one study of nearly 8000 women, the answer was *Yes*. The schizophrenia risk increased from the customary 1 percent to about 2 percent—but only when infections occurred during the second trimester (Brown et al., 2000). Maternal influenza infection during pregnancy affects brain development in monkeys as well (Short et al., 2010).

- *Does blood drawn from pregnant women whose offspring develop schizophrenia show higher-than-normal levels of antibodies that suggest a viral infection?* In several studies—including one that collected blood samples from some 20,000 pregnant women—the answer has again been *Yes* (Brown et al., 2004; Buka et al., 2001; Canetta et al., 2014).

These converging lines of evidence suggest that fetal-virus infections contribute to the development of schizophrenia. They also strengthen the U.S. government recommendation that "pregnant women need a flu shot" (CDC, 2014b).

Genetic Factors

68-5 How do genes influence schizophrenia? What factors may be early warning signs of schizophrenia in children?

Fetal-virus infections may increase the odds that a child will develop schizophrenia. But many women get the flu during their second trimester of pregnancy, and only 2 percent of them bear children who develop schizophrenia. Why are only some children at risk? Might some people be more genetically vulnerable to schizophrenia? *Yes*. The 1-in-100 odds of any person's being diagnosed with schizophrenia become about 1 in 10 among those who have a sibling or parent with the disorder. If the affected sibling is an identical twin, the odds increase to nearly 1 in 2 (**Figure 68.1**). Those odds remain the same even when the twins are raised apart (Plomin et al., 1997). (Only about a dozen such cases are on record.)

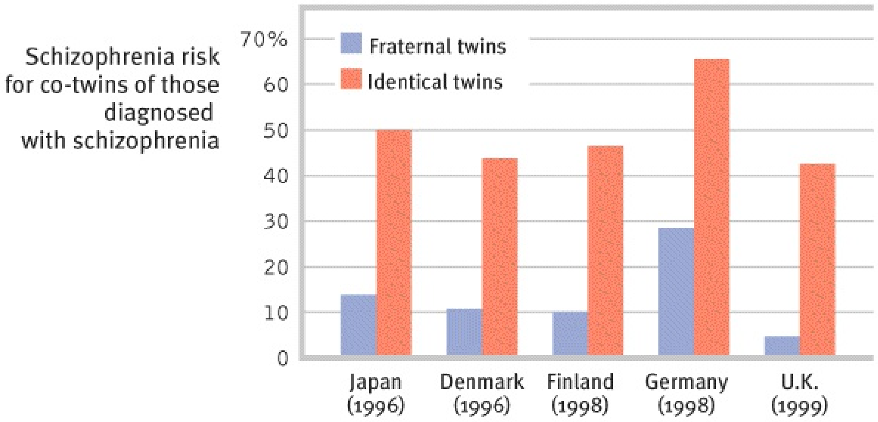


Figure 68.1
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from Gottesman, 2001.

Figure 68.1 Risk of developing schizophrenia

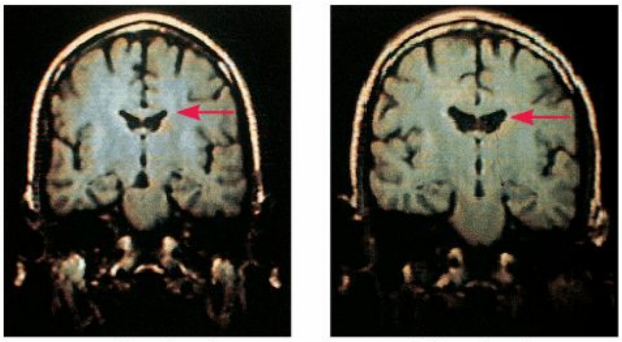
The lifetime risk of developing schizophrenia varies with one's genetic relatedness to someone having this disorder. Across countries, barely more than 1 in 10 fraternal twins, but some 5 in 10 identical twins, share a schizophrenia diagnosis.

Remember, though, that identical twins share more than their genes. They also share a prenatal environment. About two-thirds share a placenta and the blood it supplies; the other third have separate placentas. Shared placentas matter. If the co-twin of an identical twin with schizophrenia shared the placenta, the chances of developing the disorder are 6 in 10. If the identical twins had separate placentas, the co-twin's chances of developing schizophrenia drop to 1 in 10 (Davis et al., 1995; Davis & Phelps, 1995; Phelps et al., 1997). Twins who share a placenta are more likely to share the same prenatal viruses. So perhaps shared germs as well as shared genes produce identical twin similarities.

Adoption studies help untangle genetic and environmental influences. Children adopted by someone who develops schizophrenia do not "catch" the disorder. Rather, adopted children have an elevated risk if a *biological* parent is diagnosed with schizophrenia (Gottesman, 1991). Genes matter.

The search is on for specific genes that, in some combination, predispose schizophrenia-inducing brain abnormalities (**Figure 68.2**). (It is not our genes but our brains that directly control our behavior.) In the biggest-ever study of the genetics of psychiatric disorder, scientists from

35 countries pooled data from the genomes of 37,000 people with schizophrenia and 113,000 people without (Schizophrenia Working Group, 2014). They found 103 genome locations linked with this disorder. Some genes influence the effects of dopamine and other neurotransmitters in the brain. Others affect the production of *myelin*, a fatty substance that coats the axons of nerve cells and lets impulses travel at high speed through neural networks.



No schizophrenia **Schizophrenia**

Figure 68.2

Daniel Weinberger, M.D., CBDB, NIMH

Figure 68.2 Schizophrenia in identical twins

When twins differ, only the one afflicted with schizophrenia typically has enlarged, fluid-filled cranial cavities (right) (Suddath et al., 1990). The difference between the twins implies some nongenetic factor, such as a virus, is also at work.

Although genes matter, the genetic formula is not as straightforward as the inheritance of eye color. Schizophrenia is a group of disorders influenced by many genes, each with very small effects (Arnedo et al., 2015; Darby et al., 2016; International Schizophrenia Consortium, 2009). And, as we have so often seen, nature and nurture interact. Recall that *epigenetic* factors influence whether genes will be expressed. Like hot water activating a tea bag, environmental factors such as viral infections, nutritional deprivation, and maternal stress can “turn on” the genes that put some of us at higher risk for schizophrenia. Identical twins’ differing histories in the womb and beyond explain why they may show differing gene expressions (Dempster et al., 2013; Walker et al., 2010). Our heredity and our life experiences work together. Neither hand claps alone.

Thanks to our expanding understanding of genetic and brain influences on maladies such as schizophrenia, the general public more and more attributes psychiatric disorders to biological factors (Pescosolido et al., 2010). So, will scientists develop genetic tests that reveal who is at risk? If so, will people in the future subject their embryos to genetic testing (and gene repair or abortion) if they are at risk for this or some other psychological or physical malady? Might they take their egg and sperm to a genetics lab for screening before combining them to produce an embryo? Or will children be tested for genetic risks and given appropriate preventive treatments? In this brave new twenty-first-century world, such questions await answers.

Environmental Triggers for Schizophrenia

If prenatal viruses and genetic predispositions do not, by themselves, cause schizophrenia, neither do family or social factors alone. It remains true, as Susan Nicol and Irving Gottesman (1983) noted over three decades ago, that "no environmental causes have been discovered that will invariably, or even with moderate probability, produce schizophrenia in persons who are not related to" a person with schizophrenia.

Hoping to identify environmental triggers of schizophrenia, researchers have compared the experiences of high-risk children (for example, those with relatives with schizophrenia) and low-risk children. In one 2.5-year study that followed 163 teens and early-twenties adults who had two relatives with schizophrenia, the 20 percent of participants who developed schizophrenia showed social withdrawal or other abnormal behavior before the onset of the disorder (Johnstone et al., 2005). Researchers identified other possible early warning signs, including a mother whose schizophrenia was severe and long-lasting; birth complications (often involving oxygen deprivation and low birth weight); separation from parents; short attention span and poor muscle coordination; disruptive or withdrawn behavior; emotional unpredictability; poor peer relations and solo play; and childhood physical, sexual, or emotional abuse (Abel et al., 2010; Freedman et al., 1998; Schiffman et al., 2001; Susser, 1999; Welham et al., 2009).

* * *

Few of us can relate to the strange thoughts, perceptions, and behaviors of schizophrenia. Sometimes our thoughts jump around, but we rarely talk nonsensically. Occasionally we feel unjustly suspicious of someone, but we do not fear that the world is plotting against us. Often our perceptions err, but rarely do we see or hear things that are not there. We feel regret after laughing at someone’s misfortune, but we rarely giggle in response to our own bad news. At times we just want to be alone, but we do not retreat into fantasy worlds. However, millions of people around the world do talk strangely, suffer delusions, hear nonexistent voices, see things that are not there, laugh or cry at inappropriate times, or withdraw into private imaginary worlds. The quest to solve the cruel puzzle of schizophrenia continues, more vigorously than ever.

✓ Check Your Understanding

Ask Yourself

- Can you recall a time when you heard something or someone casually described as “schizophrenic”? Based on what you’ve read, how was this description accurate or inaccurate?

Test Yourself

- A person with schizophrenia who has _______________ (positive/negative) symptoms may have an expressionless face and toneless voice. These symptoms are most common with _______________ (chronic/acute) schizophrenia and are not likely to respond to drug therapy. Those with _______________ (positive/negative) symptoms are likely to experience delusions, and, if the symptoms have arisen suddenly, to be diagnosed with _______________ (chronic/acute) schizophrenia, which is much more likely to respond to drug therapy.

- What factors contribute to the onset and development of schizophrenia?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 68 REVIEW

68-1 What patterns of perceiving, thinking, and feeling characterize schizophrenia?

- People with schizophrenia display symptoms that are positive (inappropriate behaviors are present) or negative (appropriate behaviors are absent).
- Positive symptoms may include *hallucinations*, *delusions*, talking in a disorganized way, and inappropriate laughter, tears, or rage. Negative symptoms may include toneless voices, expressionless faces, or mute and rigid bodies.

68-2 How do chronic schizophrenia and acute schizophrenia differ?

- In chronic (or process) schizophrenia, the disorder develops gradually and recovery is doubtful.
- In acute (or reactive) schizophrenia, the onset is sudden, in reaction to stress, and the prospects for recovery are brighter.

68-3 What brain abnormalities are associated with schizophrenia?

- People with schizophrenia have increased dopamine receptors, which may intensify brain signals, creating positive symptoms such as hallucinations and paranoia.
- Brain abnormalities associated with schizophrenia include enlarged, fluid-filled areas and corresponding shrinkage and thinning of cerebral tissue.
- Brain scans reveal abnormal activity in the frontal lobes, thalamus, and amygdala, as well as a loss of neural connections across the brain network.

68-4 What prenatal events are associated with increased risk of developing schizophrenia?

- Possible contributing factors include maternal diabetes, older paternal age, viral infections, or famine conditions during the mother’s pregnancy, and low weight or oxygen deprivation at birth.

68-5 How do genes influence schizophrenia? What factors may be early warning signs of schizophrenia in children?

- Twin and adoption studies indicate that the predisposition to schizophrenia is inherited.
- Schizophrenia is influenced by many genes, each with very small effects. Environmental factors—including those present in the prenatal environment—may influence gene expression to enable this disorder.
- While no environmental causes invariably produce schizophrenia, possible early warning signs of later development of schizophrenia include both biological factors (a mother with severe and long-lasting schizophrenia, birth complications, short attention span, and poor muscle coordination) and psychological factors (disruptive or withdrawn behavior, emotional unpredictability, poor peer relations and solo play, separation from parents, and childhood abuse).

Multiple-Choice Questions

1. Believing that aliens are trying to steal her thoughts, Shauna wears a special hat that she designed. Her beliefs represent

a. hallucinations.
b. thickening cerebral tissue.
c. delusions.
d. a word salad.
e. insufficient dopamine receptors.

2. Over several years, Charles gradually developed schizophrenia.

Because of this, the prognosis for recovery is poor. His type of schizophrenia would be referred to as

a. acute.
b. chronic.
c. maternal.
d. catatonic.
e. positive.

3. A person with schizophrenia who is experiencing negative symptoms is likely to demonstrate

a. hallucinations.
b. delusions.
c. disorganized speech.
d. inappropriate laughter.
e. social withdrawal.

Practice FRQs

1. Julia and Eleanor are identical twins who were raised apart. Julia has developed schizophrenia, but Eleanor has not. Given what we know about how schizophrenia is strongly influenced by genetic and prenatal factors, explain how this could happen when Julia and Eleanor have identical genes and shared the same prenatal environment. Provide at least one research-supported factor that could have prompted the onset of schizophrenia in Julia.

Answer

2 points: Environmental factors also contribute to the onset of schizophrenia, which suggests why this disorder is not 100 percent heritable. Researchers have found that severe stress or trauma, such as that caused by separation from parents or childhood physical, sexual, or emotional abuse are associated with later schizophrenia in those who are genetically predisposed to the disorder. Julia's childhood may have been more stressful and traumatic than Eleanor’s, which could explain why Julia but not Eleanor developed schizophrenia.

1. Schizophrenia has been linked to brain and neurotransmitter abnormalities as well as genetics. Explain research findings related to two features of brain anatomy, one neurotransmitter, and one genetic factor that could cause someone to develop schizophrenia.

(4 points)

Module 69 Other Disorders

LEARNING TARGETS

- 69-1 Describe somatic symptom and related disorders.
- 69-2 Describe *dissociative disorders*, and explain why they are controversial.
- 69-3 Identify the three clusters of personality disorders, and explain what behaviors and brain activity characterize the antisocial personality.
- 69-4 Identify the three main eating disorders, and examine how biological, psychological, and social-cultural influences make people more vulnerable to them.

Somatic Symptom and Related Disorders

69-1 What are somatic symptom and related disorders?

Among the most common problems bringing people into doctors’ offices are “medically unexplained illnesses” (Johnson, 2008). Ellen becomes dizzy and nauseated in the late afternoon—shortly before she expects her husband home. Neither her primary care physician nor the neurologist he sent her to could identify a physical cause. They suspect her symptoms have an unconscious psychological origin, possibly triggered by her mixed feelings about her husband. Ellen has a **somatic symptom disorder** (formerly known as *somatoform disorder*), in which distressing symptoms take a somatic (bodily) form without apparent physical causes. One person may have a variety of complaints—vomiting, dizziness, blurred vision, difficulty in swallowing. Another may experience severe and prolonged pain. Culture has a big effect on people’s physical complaints and how they explain them (Kirmayer & Sartorius, 2007). In China, psychological explanations of anxiety and depression are socially less acceptable than in many Western countries, and people less often express the emotional aspects of distress. The Chinese appear more sensitive to—and more willing to report—the physical symptoms of their distress (Ryder et al., 2008). Mr. Wu, a 36-year-old technician in Hunan, illustrates one of China’s most common psychological disorders (Spitzer & Skodol, 2000). He finds work difficult because of his insomnia, fatigue, weakness, and headaches. Chinese herbs and Western medicines provide no relief. To his Chinese clinician, who treats the bodily symptoms, he seems not so much depressed as exhausted. Similar, generalized bodily complaints have often been observed in African cultures (Binitie, 1975).

somatic symptom disorder

a psychological disorder in which the symptoms take a somatic (bodily) form without apparent physical cause. (Formerly called *somatoform disorder;* see *conversion disorder* and *illness anxiety disorder*.)

Even to people in the West, somatic symptoms are familiar. To a lesser extent, we have all experienced inexplicable physical symptoms under stress. It is little comfort to be told that the problem is “all in your head.” Although the symptoms may be psychological in origin, they are nevertheless genuinely felt. A rare related disorder, more common in Freud’s day than in ours, is **conversion disorder** (also known as *functional neurological symptom disorder*), so called because anxiety presumably is converted into a physical symptom. (As we noted in Module 55, Freud’s effort to treat and understand psychological disorders stemmed from his puzzlement over ailments that had no physiological basis.) A patient with a conversion disorder might, for example, lose sensation in a way that makes no neurological sense. Yet the physical symptoms would be real; sticking pins in the affected area would produce no response. Other conversion disorder symptoms might be unexplained paralysis, blindness, or an inability to swallow. In some cases, the person may seem strangely indifferent to the problem.

conversion disorder

a disorder related to somatic symptom disorder in which a person experiences very specific, physical symptoms that are not compatible with recognized medical or neurological conditions. (Also called functional neurological symptom disorder.)

As you can imagine, somatic symptom and related disorders send people not to a psychologist or psychiatrist but to a physician. This is especially true of those who experience **illness anxiety disorder** (previously called *hypochondriasis*). In this relatively common disorder, people interpret normal sensations (a stomach cramp today, a headache tomorrow) as symptoms of a dreaded disease. Sympathy or temporary relief from everyday demands may reinforce such complaints. No amount of reassurance by any physician convinces the patient that the trivial symptoms do not reflect a serious illness. So the patient moves on to another physician, seeking and receiving more medical attention—but failing to confront the disorder's psychological root.

illness anxiety disorder

a disorder related to somatic symptom disorder in which a person interprets normal physical sensations as symptoms of a disease. (Formerly called *hypochondriasis*.)

✓ Check Your Understanding

Ask Yourself

- Can you recall (as most people can) times when you have fretted needlessly over a normal bodily sensation?

Test Yourself

- What does *somatic* mean, and how does it apply to *somatic symptom disorders?*

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Dissociative Disorders

69-2 What are *dissociative disorders*, and why are they controversial?

Among the most bewildering disorders are the rare **dissociative disorders**, in which a person’s conscious awareness *dissociates* (separates) from painful memories, thoughts, and feelings. The result may be a *fugue state*, a sudden loss of memory or change in identity, often in response to an overwhelmingly stressful situation. (Note that this explanation presumes the existence of repressed memories, which, as we noted in Modules 33 and 56, memory researchers have questioned.) Such was the case for one Vietnam veteran who was haunted by his comrades’ deaths, and who had left his World Trade Center office shortly before the 9/11 terrorist attack. Later, he disappeared. Six months later, when he was discovered in a Chicago homeless shelter, he reported no memory of his identity or family (Stone, 2006).

dissociative disorders

controversial, rare disorders in which conscious awareness becomes separated (dissociated) from previous memories, thoughts, and feelings.

Dissociation itself is not so rare. Any one of us may have a sense of being unreal, of being separated from our body, of watching ourselves as if in a movie. Sometimes we may say, “I was not myself at the time.” Perhaps you can recall getting up to go somewhere and ending up at some unintended location while your mind was preoccupied. Or perhaps you can play a well-practiced tune on a guitar or piano while talking to someone. When we face trauma, dissociative detachment may protect us from being overwhelmed by emotion.

Dissociative Identity Disorder

A massive dissociation of self from ordinary consciousness occurs in **dissociative identity disorder (DID**—formerly called *multiple personality disorder*), in which two or more distinct identities—each with its own voice and mannerisms—seem to control a person's behavior at different times. Thus, the person may be prim and proper one moment, loud and flirtatious the next. Typically, the original personality denies any awareness of the other(s).

dissociative identity disorder (DID)
a rare dissociative disorder in which a person exhibits two or more distinct and alternating personalities. (Formerly called *multiple personality disorder*.)

Multiple personalities Chris Sizemore's story, told in the book and movie *The Three Faces of Eve*, gave early visibility to what is now called *dissociative identity disorder*.

People diagnosed with DID are rarely violent. But cases have been reported of dissociations into a "good" and a "bad" (or aggressive) personality—a modest version of the Dr. Jekyll–Mr. Hyde split immortalized in Robert Louis Stevenson's story. One unusual case involved Kenneth Bianchi, accused in the "Hillside Strangler" rapes and murders of 10 California women. During a hypnosis session, Bianchi's psychologist “called forth” a hidden personality: “I’ve talked a bit to Ken, but I think that perhaps there might be another part of Ken that . . . maybe feels somewhat differently from the part that I’ve talked to. . . . Would you talk with me, Part, by saying, ‘I’m here’?” Bianchi answered “Yes” and then claimed to be “Steve” (Watkins, 1984).

Speaking as Steve, Bianchi stated that he hated Ken because Ken was nice and that he (Steve), aided by a cousin, had murdered women. He also claimed Ken knew nothing about Steve’s existence and was innocent of the murders. Was Bianchi’s second personality a trick, simply a way of disavowing responsibility for his actions? Indeed, Bianchi—a practiced liar who had read about multiple personality in psychology books—was later convicted.

Understanding Dissociative Identity Disorder

Skeptics question DID. First, instead of being a true disorder, could DID be an extension of our normal capacity for personality shifts? Nicholas Spanos (1986, 1994, 1996) asked college students to pretend they were accused murderers being examined by a psychiatrist. Given the same hypnotic treatment Bianchi received, most spontaneously expressed a second personality. This discovery made Spanos wonder: Perhaps dissociative identities are simply a more extreme version of the varied “selves” we normally present—as when we display a goofy, loud self while hanging out with friends, and a subdued, respectful self around grandparents. Are clinicians who discover multiple personalities merely triggering role playing by fantasy-prone people? Do these people, like actors who commonly report “losing themselves” in their roles, then convince themselves of the authenticity of their own role enactments? Spanos was no stranger to this line of thinking. In a related research area, he had also raised these questions about the hypnotic state. Because most DID patients are highly hypnotizable, whatever explains one condition—dissociation or role playing—may help explain the other.

> “*Pretense may become reality.*”

Chinese proverb

Skeptics also find it suspicious that the disorder has such a short and localized history. Between 1930 and 1960, the number of North American DID diagnoses averaged 2 per decade. By the 1980s, when the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (DSM) contained the first formal code for this disorder, the number had exploded to more than 20,000 (McHugh, 1995a). The average number of displayed personalities also mushroomed—from 3 to 12 per patient (Goff & Simms, 1993). Although diagnoses are increasing in countries where DID has been publicized, the disorder is much less prevalent outside North America (Lilienfeld, 2017). In Britain, diagnosis of DID—which some have considered "a wacky American fad" (Cohen, 1995)—has been rare.

The Mankato Free Press/AP Photo

Widespread dissociation Shirley Mason was a psychiatric patient diagnosed with dissociative identity disorder. Her life formed the basis of the bestselling book *Sybil* (Schreiber, 1973) and of two movies. Some argue that the book and movies' popularity fueled the dramatic rise in diagnoses of DID. Skeptics wonder whether Mason actually had the disorder (Nathan, 2011).

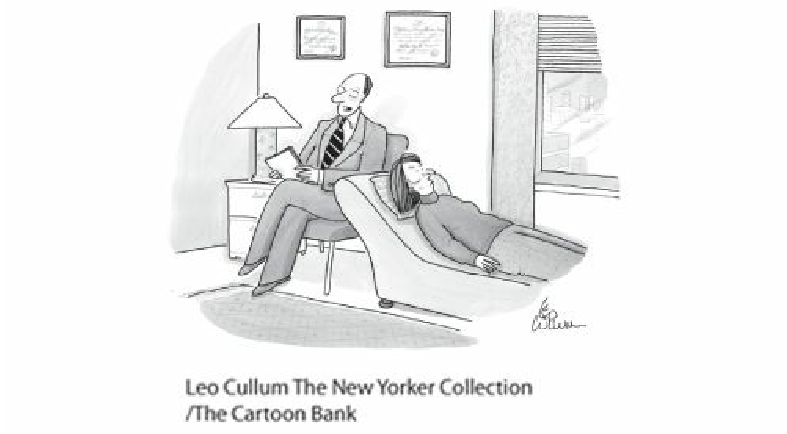
Such findings, skeptics have noted, point to a disorder of suggestible, fantasy-prone people created by therapists in a particular social context (Giesbrecht et al., 2008, 2010; Lynn et al., 2014; Merskey, 1992). Clients do not enter therapy saying "Allow me to introduce myselves." Instead, charge the critics, some therapists go fishing for multiple personalities: “*Have you ever felt like another part of you does things you can’t control? Does this part of you have a name? Can I talk to the angry part of you?*” Once clients permit a therapist to talk, by name, “to the part of you that says those angry things,” they begin acting out the fantasy. The result may be the experience of another self.

Other researchers and clinicians believe DID is a real disorder. They cite findings of distinct body and brain states associated with differing personalities (Putnam, 1991). Abnormal brain anatomy and activity can also accompany DID. Brain scans show shrinkage in areas that aid memory and detection of threat (Vermetten et al., 2006). Heightened activity appears in brain areas associated with the control and inhibition of traumatic memories (Elzinga et al., 2007).

Both the psychodynamic and learning perspectives have interpreted DID symptoms as ways of coping with anxiety. Some psychodynamic theorists see them as defenses against the anxiety caused by the eruption of unacceptable impulses. In this view, a second personality enables the discharge of forbidden impulses. Learning theorists see dissociative disorders as behaviors reinforced by anxiety reduction.

> “*Though this be madness, yet there is method in’t.*”
>
> *William Shakespeare,* Hamlet, *1600*

Some clinicians include dissociative disorders under the umbrella of posttraumatic stress disorder—a natural, protective response to traumatic experiences during childhood (Brand et al., 2016; Spiegel, 2008). Many people being treated for DID recall being physically, sexually, or emotionally abused as children (Gleaves, 1996; Lilienfeld et al., 1999). In one study of 12 murderers diagnosed with DID, 11 had suffered severe, torturous child abuse (Lewis et al., 1997). One had been set afire by his parents. Another had been used in child pornography and was scarred from being made to sit on a stove burner. Some critics wonder, however, whether vivid imagination or therapist suggestion contributed to such recollections (Kihlstrom, 2005).



Leo Cullum The New Yorker Collection
/The Cartoon Bank

"Would it be possible to speak with the personality that pays the bills?"

So the debate continues. On one side are those who believe multiple personalities are the desperate efforts of people trying to detach from a horrific existence. On the other are skeptics who think DID is constructed out of the therapist-client interaction and acted out by fantasy-prone, emotionally vulnerable people. If the skeptics' view wins, predicted psychiatrist Paul McHugh (1995b), "this epidemic will end in the way that the witch craze ended in Salem. The [multiple personality phenomenon] will be seen as manufactured."

✓ Check Your Understanding

Ask Yourself

- Do you ever flip between displays of different aspects of your personality? How is your experience similar to and different from the symptoms of dissociative identity disorder?

Test Yourself

- The psychodynamic and learning perspectives agree that dissociative identity disorder symptoms are ways of dealing with anxiety. How do their explanations differ?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Personality Disorders

69-3 What are the three clusters of personality disorders? What behaviors and brain activity characterize the antisocial personality?

The inflexible and enduring behavior patterns of **personality disorders** interfere with social functioning. The ten disorders in DSM-5 tend to form three clusters, characterized by

- anxiety, such as a fearful sensitivity to rejection that predisposes the withdrawn *avoidant personality disorder*.
- eccentric or odd behaviors, such as the emotionless disengagement of *schizotypal personality disorder*.
- dramatic or impulsive behaviors, such as the attention-getting *borderline personality disorder*, the self-focused and self-inflating *narcissistic personality disorder*, and—what we next discuss as an in-depth example—the callous, and often dangerous, *antisocial personality disorder*.

personality disorders

inflexible and enduring behavior patterns that impair social functioning.

Antisocial Personality Disorder

People with **antisocial personality disorder**, usually male, can display symptoms by age 8. Their lack of conscience becomes plain before age 15, as they begin to lie, steal, fight, or display unrestrained sexual behavior (Cale & Lilienfeld, 2002). Not all children with these traits become antisocial adults. (Note: “Antisocial” means disruptive, not just unsociable.) Those who do (about half of them) will generally act in violent or otherwise criminal ways, be unable to keep a job, and, if they have a spouse or children, behave irresponsibly toward them (Farrington, 1991). People with antisocial personality disorder (sometimes called *sociopaths* or *psychopaths*) may show lower *emotional intelligence*—the ability to understand, manage, and perceive emotions (Ermer et al., 2012).

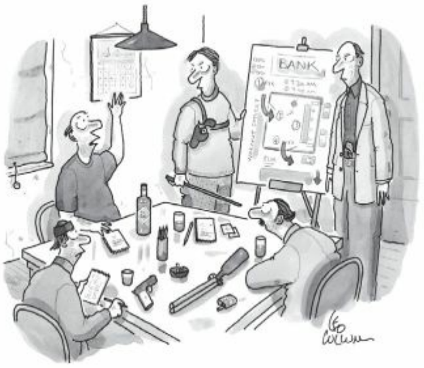
antisocial personality disorder

a personality disorder in which a person (usually a man) exhibits a lack of conscience for wrongdoing, even toward friends and family members; may be aggressive and ruthless or a clever con artist.

Despite their remorseless and sometimes criminal behavior, criminality is not an essential component of antisocial behavior (Skeem & Cooke, 2010). Moreover, many criminals do not fit the description of antisocial personality disorder. Why? Because they're not impulsive (Geurts et al., 2016). Rather, they actually show responsible concern for their friends and family members. When the antisocial personality combines a keen intelligence with amorality, the result may be a charming and clever con artist—or a fearless, focused, ruthless soldier, surgeon, or CEO (Dutton, 2012; Schutte et al., 2016).

JEFF TUTTLE/Tribune News Service/Newscom

No remorse Dennis Rader, known as the "BTK killer" in Kansas, was convicted in 2005 of killing 10 people over a 30-year span. Rader exhibited the extreme lack of conscience that marks antisocial personality disorder.



Leo Cullum The New Yorker Collection/The Cartoon Bank

“Thursday is out. I have jury duty.”

Many criminals, like this one, exhibit a sense of conscience and responsibility in other areas of their life, and thus do not exhibit antisocial personality disorder.

Antisocial personalities behave impulsively, and then feel and fear little (Fowles & Dindo, 2009). Their impulsivity can have horrific consequences (Camp et al., 2013). Consider the case of Henry Lee Lucas. He killed his first victim when he was 13. He felt little regret then or later. During his years of crime, he brutally murdered 157 women, men, and children. For the last six years of his reign of terror, Lucas teamed with Ottis Elwood Toole, who reportedly slaughtered people he “didn’t think was worth living anyhow” (Darrach & Norris, 1984).

Understanding Antisocial Personality Disorder

Antisocial personality disorder is woven of both biological and psychological strands. Twin and adoption studies reveal that biological relatives of people with antisocial and unemotional tendencies are at increased risk for antisocial behavior (Frisell et al., 2012; Kendler et al., 2015b). People with antisocial personalities sometimes spread their genes to future generations by marrying others who have antisocial personalities (Weiss et al., 2017). No single gene codes for a complex behavior such as crime. Molecular geneticists have, however, identified some specific genes that are more common in those with antisocial personality disorder (Gunter et al., 2010).

The genetic vulnerability of people with antisocial and unemotional tendencies appears as low arousal in response to threats. Awaiting aversive events, such as electric shocks or loud noises, they show little autonomic nervous system arousal (Hare, 1975; Hoppenbrouwers et al., 2016). Long-term studies show that their stress hormone levels were lower than average as teenagers, before committing any crime (**Figure 69.1**). And those who were slow to develop conditioned fears at age 3 were also more likely to commit a crime later in life (Gao et al., 2010). Other studies have found that preschool boys who later became aggressive or antisocial adolescents tended to be impulsive, uninhibited, unconcerned with social rewards, and low in anxiety (Caspi et al., 1996; Tremblay et al., 1994).

Data from Magnusson, 1990.

Figure 69.1 Cold-blooded arousability and risk of crime

Levels of the stress hormone adrenaline were measured in two groups of 13-year-old Swedish boys. In both stressful and nonstressful situations, those who would later be convicted of a crime as 18- to 26-year-olds showed relatively low arousal.

Traits such as fearlessness and dominance can be adaptive. If channeled in more productive directions, fearlessness may lead to athletic stardom, adventurism, or courageous heroism (Smith et al., 2013). In one analysis, 42 American presidents scored higher than the general population on such traits as fearlessness and dominance (Lilienfeld et al., 2012, 2016). Patient S. M., a 49-year-old woman who experienced damage to her amygdala, showed fearlessness and impulsivity but also displayed acts of heroism (Lilienfeld et al., 2017). For example, she gave a man in need her only coat and scarf. Befriending a child with cancer, how did she respond? She cut her hair short and donated it to the Locks of Love charity.

Genetic influences, often in combination with negative environmental factors such as childhood abuse, family instability, or poverty, help wire the brain (Dodge, 2009). In people with antisocial criminal tendencies, the emotion-controlling amygdala is smaller (Pardini et al., 2014). The frontal lobes are also less active, as Adrian Raine (1999, 2005) found when he compared PET scans of 41 murderers' brains with those from people of similar age and sex (**Figure 69.2**). The frontal lobes help control impulses. The reduced activation was especially apparent in those who murdered impulsively. In a follow-up study, Raine and his team (2000) found that violent repeat offenders had 11 percent less frontal lobe tissue than normal. This helps explain why people with antisocial personality disorder exhibit marked deficits in frontal lobe cognitive functions, such as planning, organization, and inhibition (Morgan & Lilienfeld, 2000). Compared with people who feel and display empathy, their brains also respond less to facial displays of others' distress, which may contribute to their lower emotional intelligence (Deeley et al., 2006).

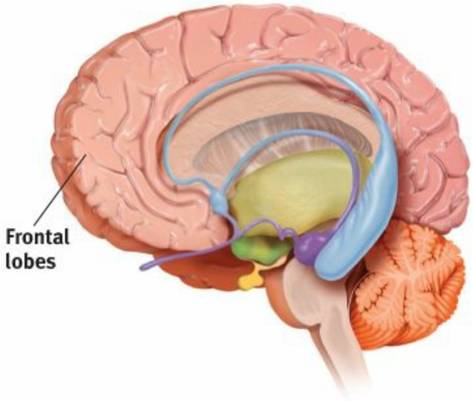

Figure 69.2
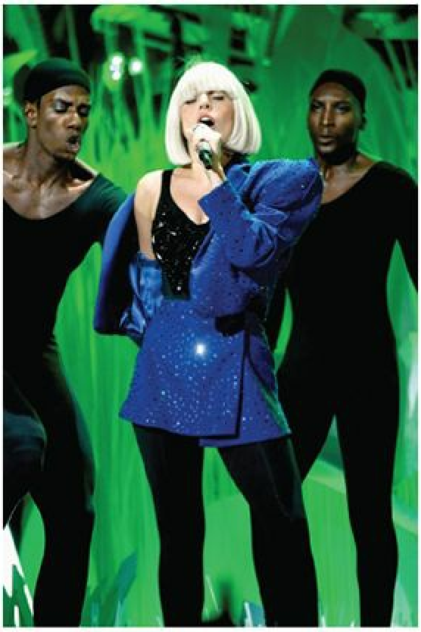
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 69.2 Murderous minds

Researchers have found reduced activation in a murderer’s frontal lobes. This brain area (shown in a left-facing brain) helps brake impulsive, aggressive behavior (Raine, 1999).

A biologically based fearlessness, as well as early environment, helps explain an unusual family reunion. Long-separated sisters Joyce Lott, 27, and Mary Jones, 29, came together at a place that normally separates family members rather than brings them together—a South Carolina prison where both were sent on drug charges. After a newspaper story about their reunion, their long-lost half-brother Frank Strickland called. But he had his own problem: He was stuck in jail on drug, burglary, and larceny charges (Shepherd et al., 1990). The genes that put people at risk for antisocial behavior also put people at risk for substance use disorders, which may help explain why these disorders often appear in combination (Dick, 2007).

Genetics alone do not tell the whole story of antisocial crime, however. In another Raine-led study (1996), researchers checked criminal records on nearly 400 Danish men at ages 20 to 22. All these men either had experienced biological risk factors at birth (such as premature birth) or came from family backgrounds marked by poverty and family instability. The researchers then compared each of these two groups with a third *biosocial* group (people whose lives were marked by *both* those biological and social risk factors). The biosocial group had double the risk of committing crime. Similar findings emerged from a famous study that followed 1037 children for a quarter-century: Two combined factors—childhood maltreatment and a gene that altered neurotransmitter balance—predicted antisocial problems (Caspi et al., 2002). Neither “bad” genes alone nor a “bad” environment alone predisposed later antisocial behavior. Rather, genes predisposed some children to be more sensitive to maltreatment. Within “genetically vulnerable segments of the population,” environmental influences matter—for better or for worse (Belsky & Pluess, 2009; Moffitt, 2005).



Jeff Kravitz/Getty Images

Battling with body image Many celebrities, including Lady Gaga, have struggled publicly with eating disorders.

With antisocial behavior, as with so much else, nature and nurture interact and the biopsychosocial perspective helps us understand the whole story. To explore the neural basis of antisocial personality disorder, neuroscientists are trying to identify brain activity differences in criminals who display symptoms of this disorder. Shown emotionally evocative photographs, such as a man holding a knife to a woman's throat, criminals with antisocial personality disorder display blunted heart rate and perspiration responses, and less activity in brain areas that typically respond to emotional stimuli (Harenski et al., 2010; Kiehl & Buckholtz, 2010). They also have a larger and hyper-reactive dopamine reward system, which predisposes their impulsive drive to do something rewarding despite the consequences (Buckholtz et al., 2010; Glenn et al., 2010). Such data provide another reminder: Everything psychological is also biological.

Eating Disorders

69-4 What are the three main eating disorders, and how do biological, psychological, and social-cultural influences make people more vulnerable to them?

Our bodies are naturally disposed to maintain a steady weight, including storing energy for times when food becomes unavailable. But sometimes psychological influences overwhelm biological wisdom. This becomes painfully clear in three eating disorders.

- **Anorexia nervosa** typically begins as a weight-loss diet. People with anorexia—usually female adolescents, but some women, men, and boys as well—drop significantly below normal weight. Yet they feel fat, fear being fat, diet obsessively, and sometimes exercise excessively. About half of those with anorexia display a binge-purge-depression cycle.
- **Bulimia nervosa**, unlike anorexia, is marked by weight fluctuations within or above normal ranges, making the condition easier to hide. Bulimia may also be triggered by a weight-loss diet, broken by gorging on forbidden foods. People with this disorder—mostly women in their late teens or early twenties (but also some men)—eat in spurts, sometimes influenced by negative emotion or by friends who are bingeing (Crandall, 1988; Haedt-Matt & Keel, 2011). In a cycle of repeating episodes, overeating is followed by compensatory vomiting, laxative use, fasting, or excessive exercise (Wonderlich et al., 2007). Preoccupied with food (craving sweet and high-fat foods), and fearful of becoming overweight, binge-purge eaters experience bouts of depression, guilt, and anxiety during and following binges (Hinz & Williamson, 1987; Johnson et al., 2002).
- Those with **binge-eating disorder** engage in significant bouts of overeating, followed by remorse. But they do not purge, fast, or exercise excessively and thus may be overweight.

anorexia nervosa

an eating disorder in which a person (usually an adolescent female) maintains a starvation diet despite being significantly underweight; sometimes accompanied by excessive exercise.

bulimia nervosa

an eating disorder in which a person’s binge eating (usually of high-calorie foods) is followed by inappropriate weight-loss promoting behavior, such as vomiting, laxative use, fasting, or excessive exercise.

binge-eating disorder

significant binge-eating episodes, followed by distress, disgust, or guilt, but without the compensatory behavior that marks bulimia nervosa.

A U.S. National Institute of Mental Health-funded study reported that, at some point during their lifetime, 0.6 percent of Americans met the criteria for anorexia, 1 percent for bulimia, and 2.8 percent for binge-eating disorder (Hudson et al., 2007). Anorexia and bulimia can be deadly. They harm the body and mind, resulting in shorter life expectancy and greater risk of suicide and nonsuicidal self-injury (Cucchi et al., 2016; Fichter & Quadflieg, 2016; Smith et al., 2016).

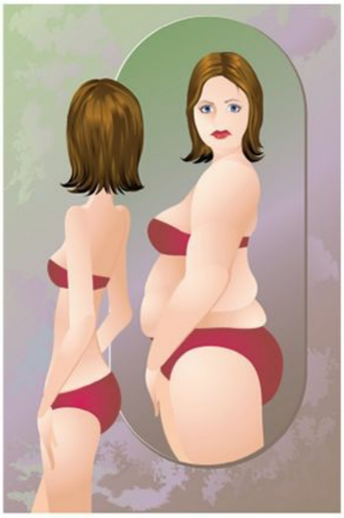
“Gee, I had no idea you were married to a supermodel.”

Understanding Eating Disorders

Eating disorders are *not* (as some have speculated) a telltale sign of childhood sexual abuse (Smolak & Murnen, 2002; Stice, 2002). The family environment may influence eating disorders in other ways, however. For example, the families of those with anorexia tend to be competitive, high-achieving, and protective (Ahrén et al., 2013; Berg et al., 2014; Yates, 1989, 1990).

Those with eating disorders often have low self-evaluations, set perfectionist standards, fret about falling short of expectations, and are intensely concerned with how others perceive them (Culbert et al., 2015; Farstad et al., 2016; Yiend et al., 2014). Some of these factors also predict teen boys’ pursuit of unrealistic muscularity (Ricciardelli & McCabe, 2004).

Heredity also matters. Identical twins share these disorders more often than fraternal twins do (Culbert et al., 2009; Klump et al., 2009; Root et al., 2010). Scientists are searching for culprit genes, which may influence the body’s available serotonin and estrogen (Klump & Culbert, 2007). Data from 15 studies indicate that having a gene that reduces available serotonin adds 30 percent to a person’s risk of anorexia or bulimia (Calati et al., 2011).



artbyjulie/Getty Images

A distorted body image underlies anorexia.

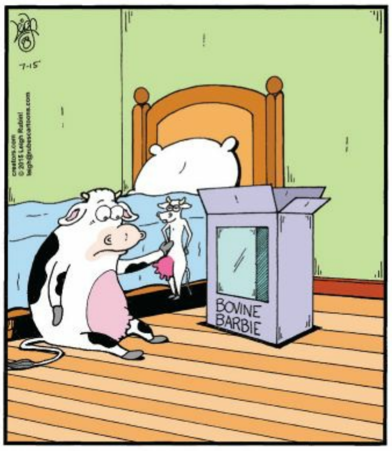
But eating disorders also have cultural and gender components. Ideal shapes vary across culture and time. In countries with high rates of poverty—where plump means prosperous and thin can signal poverty or illness—bigger often seems better (Knickmeyer, 2001; Swami et al., 2010). Bigger less often seems better in Western cultures, where, according to 222 studies of 141,000 people, the rise in eating disorders in the last half of the twentieth century coincided with a dramatic increase in women having a poor body image (Feingold & Mazzella, 1998).

Those most vulnerable to eating disorders are also those (usually women or gay men) who most idealize thinness and have the greatest body dissatisfaction (Feldman & Meyer, 2010; Kane, 2010; Stice et al., 2010). Should it surprise us, then, that women who view real and doctored images of unnaturally thin models and celebrities often feel ashamed, depressed, and dissatisfied with their own bodies—the very attitudes that predispose eating disorders (Grabe et al., 2008; Myers & Crowther, 2009; Tiggemann & Miller, 2010)? Researchers tested this modeling idea by giving some adolescent girls (but not others) a 15-month subscription to an American teen-fashion magazine (Stice et al., 2001). Compared with those who had not received the magazine, vulnerable girls—defined as those who were already dissatisfied, idealizing thinness, and lacking social support—exhibited increased body dissatisfaction and eating disorder tendencies.

Even ultra-thin models do not reflect the impossible standard of the old classic Barbie doll, who had, when adjusted to a height of 5 feet 7 inches, a 32–16–29 figure (in centimeters, 81–41–74) (Norton et al., 1996).

> “*Why do women have such low self-esteem? There are many complex psychological and societal reasons, by which I mean Barbie.*”
>
> *Dave Barry, 1999*

There is, however, more to body dissatisfaction and anorexia than media effects (Ferguson et al., 2011). Peer influences, such as teasing, also matter. Nevertheless, the sickness of today’s eating disorders stems in part from today’s weight-obsessed culture—a culture that says “fat is bad” in countless ways, that motivates millions of women to diet constantly, and that invites eating binges by pressuring women to live in a constant state of semistarvation. One former model recalled walking into a meeting with her agent, starving and with her organs failing due to anorexia (Caroll, 2013). Her agent’s greeting: “Whatever you are doing, keep doing it.”



Leigh Rubes/Creators Syndicate, Inc.

“Up until that point, Bernice had never once had a problem with low self-esteem.”

Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Too thin? Anorexia was identified and named in the 1870s, when it appeared among affluent adolescent girls (Brumberg, 2000). Many worry that today's superthin models make self-starvation seem fashionable. In response to this concern, British advertising regulators banned this advertisement because the female model appeared "unhealthily thin."

Most people diagnosed with an eating disorder do improve. In one 22-year study, 2 in 3 women with anorexia nervosa or bulimia nervosa had recovered (Eddy et al., 2017). It's also possible to prevent people from developing these disorders. Interactive programs that teach people (especially girls over age 15) to accept their bodies reduce the likelihood of an eating disorder (Beintner et al., 2012; Melioli et al., 2016; Vocks et al., 2010). By combating cultural learning, those at risk for eating disorders may instead live long and healthy lives.

* * *

The bewilderment, fear, and sorrow caused by psychological disorders are real. But, as our next topic—therapy—shows, hope, too, is real.

Ask Yourself

- Given what we have learned in earlier units about the powers and limits of parental influence, how much do you think parents affect the risk of a child's developing antisocial personality disorder?

Test Yourself

- How do biological and psychological factors contribute to antisocial personality disorder?
- People with _______________ (anorexia nervosa/bulimia nervosa) continue to want to lose weight even when they are underweight. Those with _______________ (anorexia nervosa/bulimia nervosa) tend to have weight that fluctuates within or above normal ranges.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 69 REVIEW

69-1 What are somatic symptom and related disorders?

- *Somatic symptom disorder* presents a somatic (bodily) symptom—a physiologically unexplained but genuinely felt ailment.
- In the related *conversion disorder* (also called functional neurological symptom disorder), anxiety appears converted to a physical symptom that has no reasonable neurological or medical basis.
- The more common *illness anxiety disorder*, another related disorder, involves the interpretation of normal sensations as a dreaded disorder.

69-2 What are *dissociative disorders*, and why are they controversial?

- *Dissociative disorders* are conditions in which conscious awareness seems to become separated from previous memories, thoughts, and feelings.
- Skeptics note that *dissociative identity disorder*, formerly known as multiple personality disorder, increased dramatically in the late twentieth century, that it is rarely found outside North America, and that it may reflect role-playing by people who are vulnerable to therapists' suggestions. Others view this disorder as a manifestation of feelings of anxiety, or as a response learned when behaviors are reinforced by anxiety reduction.

69-3 What are the three clusters of personality disorders? What behaviors and brain activity characterize the antisocial personality?

- *Personality disorders* are disruptive, inflexible, and enduring behavior patterns that impair social functioning.

- These disorders form clusters, based on three main characteristics: (1) anxiety; (2) eccentric or odd behaviors; and (3) dramatic or impulsive behaviors.
- *Antisocial personality disorder* is characterized by a lack of conscience and, sometimes, by aggressive and fearless behavior. The amygdala is smaller and the frontal lobes less active in people with this disorder, leading to impaired frontal lobe cognitive functions and decreased responsiveness to others' distress. Genetic predispositions may interact with the environment to produce these characteristics.

69-4 What are the three main eating disorders, and how do biological, psychological, and social-cultural influences make people more vulnerable to them?

- Anorexia nervosa, bulimia nervosa, and binge-eating disorder are the three main eating disorders.
- Despite being significantly underweight, people with *anorexia nervosa* (usually adolescent females) continue to diet because they view themselves as fat.
- Those with *bulimia nervosa* (usually females in their late teens and twenties) secretly binge and then compensate by purging, fasting, or excessively exercising. Unlike anorexia, bulimia is marked by weight fluctuations within or above normal ranges.
- Those with *binge-eating disorder* binge but do not follow bingeing with purging, fasting, or exercise.
- Low self-esteem, perfectionism, concern with others' perceptions, and cultural pressure—which include body ideals that vary across time and place, often perpetuated through media—interact with stressful life experiences and genetics to produce eating disorders.

Multiple-Choice Questions

1. Adela regularly interprets everyday aches and pains, such as stomach cramps and headaches, as serious medical problems. Her doctor is unable to convince her that her problems are not serious. Adela suffers from

a. dissociative identity disorder.
b. antisocial personality disorder.
c. a fugue state.
d. illness anxiety disorder.
e. anorexia nervosa.

2. Karl, a 45-year-old barber, had worked in the same shop his entire life. Last year he disappeared and was found working as a car mechanic known as “K” 300 miles away, saying he had no memory of his former life. Karl’s clinical diagnosis would most likely be

a. schizophrenia.
b. antisocial personality disorder.
c. a fugue state.
d. a conversion disorder.
e. dissociative identity disorder.

3. Antisocial personality disorder is most often characterized by

a. violence.
b. lack of conscience.
c. mood swings.
d. unexplained physical symptoms.
e. committing serial murders.

Practice FRQs

1. Contrast and compare the following eating disorders:

- Anorexia nervosa
- Bulimia nervosa
- Binge-eating disorder

Answer

1 point: Individuals with anorexia nervosa have a distorted body image: They feel “fat” and continue to follow a starvation diet to lose weight even after they’ve become significantly underweight. Onset is usually during adolescence and in females, though men may also develop this disorder. Page 712

1 point: Individuals with bulimia nervosa are also distressed about their weight. These individuals alternate between bingeing and purging. Most people with the disorder are women in their late teens or twenties, but men may also suffer from bulimia. Page 713

1 point: Individuals with binge-eating disorder binge without purging. Page 713

2. Dissociative identity disorder (DID) is among the most controversial of all psychological disorders. Briefly describe the disorder. Then, provide one piece of evidence that supports the existence of the disorder and one piece of evidence that would indicate the disorder might not be genuine.

AP® EXAM PRACTICE QUESTIONS

Multiple-Choice Questions

1. When psychological symptoms interfere with daily life they are considered

a. catatonic.
b. flat.
c. dysfunctional.
d. positive.
e. negative.

2. The risk of bipolar disorder dramatically increases if you

a. have suffered a debilitating injury.
b. have an adoptive parent who has the disorder.
c. have a biological parent with the disorder.
d. have a life-threatening illness.
e. have above-average intelligence.

3. Jessica and Harper are identical twins. Jessica has been diagnosed with a psychological disorder. Harper is most at risk for developing the same disorder if Jessica is diagnosed with

a. agoraphobia.
b. antisocial personality disorder.
c. bipolar disorder.
d. bulimia nervosa.

e. schizophrenia.

4. In the United States, suicide rates are highest

a. during the middle of the winter.
b. among those with depression who are beginning to recover.
c. among women ages 45–55.
d. among married people.
e. among Hispanic men.

5. People with obsessive-compulsive disorder may report feeling less anxious after they clean, which causes them to want to clean again the next time they feel anxious. This demonstrates the principle of

a. stimulus generalization.
b. stimulus discrimination.
c. punishment.
d. spontaneous recovery.
e. reinforcement.

6. A split from reality that shows itself in disorganized speech, disturbed perceptions, and/or diminished or inappropriate emotional expression is associated with which psychological disorder?

a. Schizophrenia
b. Phobias
c. Depressive disorders
d. Bipolar disorder
e. Anxiety disorders

7. The nearly 1-in-100 odds of any person being diagnosed with schizophrenia become about 1 in 10 among those

a. who also suffer from an anxiety disorder.
b. whose parent has the disorder.
c. who have been diagnosed with a depressive disorder.
d. who live with someone diagnosed with schizophrenia.
e. whose fraternal twin has schizophrenia.

8. Which of the following can be characterized as a compulsion?

a. Worry about exposure to germs or toxins
b. Fear that something terrible is about to happen
c. Concern with making sure things are in symmetrical order
d. Anxiety when objects are not lined up in an exact pattern
e. Checking repeatedly to see if doors are locked

9. Amanda has been diagnosed with schizophrenia. Her main symptom is hearing voices that are not there, which is known as a

a. word salad.
b. delusion.
c. paranoid thought.
d. rumination.
e. hallucination.

0. Convinced that she is fat, Lu diets excessively and spends at least one hour a day in the gym before school. Lu has gotten very thin, and her parents are concerned that she may be developing

a. illness anxiety disorder.
b. binge-eating disorder.
c. bulimia nervosa.
d. anorexia nervosa.
e. DID.

1. What is the most common reason people seek mental health services?

a. Depression
b. Bipolar disorder
c. Posttraumatic stress disorder
d. Dissociative identity disorder
e. Illness anxiety disorder

2. Brain scans of people with schizophrenia show

a. abnormally high brain activity in the frontal lobes.
b. an increase in the brain waves that reflect synchronized neural

firing.

c. abnormal activity in multiple brain areas.
d. decreased activity in the amygdala.
e. a lack of dopamine receptors.

3. Bert feels no regret after violating others’ rights and is quite clever at manipulating those around him. Bert would most likely be diagnosed with

a. antisocial personality disorder.
b. avoidant personality disorder.
c. schizotypal personality disorder.
d. histrionic personality disorder.
e. narcissistic personality disorder.

4. What term refers to thoughts about who or what we blame for our successes and failures?

a. Stability
b. Emotional memory
c. The social-cognitive perspective
d. Explanatory style
e. Dissociative reasoning

5. Psychologists have found _____ in every known culture.

a. bulimia nervosa
b. anorexia nervosa
c. susto
d. schizophrenia
e. taijin-kyofusho

6. Kayla’s uncle fought in an overseas war zone. After returning home, he finds it difficult to sleep and has a feeling of near constant anxiety. A psychiatrist would most likely offer him treatment for

a. posttraumatic stress disorder.
b. illness anxiety disorder.

c. panic disorder.
d. conversion disorder.
e. bipolar disorder.

7. Modern psychologists contend that all behavior, whether it is called normal or disordered, arises from the interaction of

a. genetics and physiology.
b. children and parents.
c. experience and wisdom.
d. inborn tendencies and drives.
e. nature and nurture.

8. Which of the following are symptoms of generalized anxiety disorder?

a. Unexplainable and continual tension
b. Sudden episodes of intense dread
c. Irrational and intense fear of a specific object or situation
d. Repetitive thoughts or actions
e. Nightmares for weeks after a traumatic event

9. Worried that she may hit her father, Maeve finds that her hand has suddenly gone numb. Her most likely diagnosis would be

a. a phobia.
b. generalized anxiety disorder.
c. a conversion disorder.
d. chronic schizophrenia.
e. illness anxiety disorder.

0. An MRI shows that a patient has enlarged ventricles in the brain. A likely diagnosis would be

I. schizophrenia.
II. bipolar disorder.
III. DID.

a. I only
b. II only

c. III only
d. I & II only
e. I & III only

Free-Response Questions

1. After reading her AP® Psychology text, Jane starts to wonder if all young people have some kind of psychological disorder. First, briefly explain what you might say to Jane about the criteria psychologists use when diagnosing mental illnesses. Then, briefly explain the symptoms associated with the following diagnoses and how age might be related to each diagnosis:

- ADHD
- Anorexia nervosa
- OCD
- Bipolar disorder

Rubric for Free-Response Question 1

1 point: Psychologists define a disorder as a significant disturbance in an individual's cognition, emotion regulation, or behavior that is dysfunctional or maladaptive. Jane's general statement that all young people have a psychological disorder doesn't make sense in this context: It's not likely that all young people have significant disturbances that interfere with their day-to-day lives. Page 666

1 point: The symptoms of ADHD include inattention, hyperactivity, and impulsivity. ADHD is diagnosed more often in young people, but some adults are also diagnosed with ADHD. Page 671

1 point: Individuals with anorexia nervosa have a distorted body image: They feel "fat" and continue to follow a starvation diet to lose weight even after they've become significantly underweight. These symptoms usually appear in adolescent females, but males and older women may also suffer from this disorder. Page 712

1 point: Individuals with OCD experience unwanted repetitive thoughts (obsessions) and actions (compulsions). This disorder is most commonly diagnosed in teens and young adults. Page 679

1 point: People with bipolar disorder will alternate between feelings of mania and feelings of depression. This disorder affects males and females equally and may be diagnosed at any age. Page 687

2. Describe what the terms *obsession* and *compulsion* refer to in the context of obsessive-compulsive disorder (OCD). Then, do the following:

- Provide an example of a common obsession experienced by individuals with OCD.
- Provide an example of a common compulsion experienced by individuals with OCD.
- Briefly explain how the learning perspective explains compulsions.
- Briefly explain how the biological perspective explains compulsions.

(6 points)

3. Researchers have been very interested in the way that various neurotransmitters affect psychological disorders. For each of the following neurotransmitters, describe one disorder that could be affected, and indicate whether the disorder is due to an abundance or scarcity of the neurotransmitter.

- Norepinephrine
- Serotonin
- Dopamine

UNIT XIII Treatment of Abnormal Behavior

Steve Debenport/Getty Images

MODULES

70 Introduction to Therapy, and Psychodynamic and Humanistic Therapies

71 Behavior, Cognitive, and Group Therapies

72 Evaluating Psychotherapies

73 The Biomedical Therapies and Preventing Psychological Disorders

Kay Redfield Jamison is both an award-winning clinical psychologist and a world expert on the emotional extremes of bipolar disorder. She knows her subject firsthand: “For as long as I can remember,” she recalled in *An Unquiet Mind*, “I was frighteningly, although often wonderfully, beholden to moods. Intensely emotional as a child, mercurial as a young girl, first severely depressed as an adolescent, and then unrelentingly caught up in the cycles of manic-depressive illness [now known as bipolar disorder] by the time I began my professional life, I became, both by necessity and intellectual inclination, a student of moods” (1995, pp. 4–5). Jamison’s life was blessed with times of intense sensitivity and passionate energy. But like her father’s, it was also sometimes plagued by reckless spending, racing conversation, and sleeplessness, alternating with swings into “the blackest caves of the mind.”

Then, “in the midst of utter confusion,” she made a life-changing decision. Risking professional embarrassment, she made an appointment with a therapist, a psychiatrist she would visit weekly for years to come.

> He kept me alive a thousand times over. He saw me through madness, despair, wonderful and terrible love affairs, disillusionments and triumphs, recurrences of illness, an almost fatal suicide attempt, the death of a man I greatly loved, and the enormous pleasures and aggravations of my professional life. . . . He was very tough, as well as very kind, and even though he understood more than anyone how much I felt I was losing—in energy, vivacity, and originality—by taking medication, he never [lost] sight of the overall perspective of how costly, damaging, and life threatening my illness was. . . . Although I went to him to be treated for an illness, he taught me . . . the total beholdenness of brain to mind and mind to brain (pp. 87–88).

“Psychotherapy heals,” Jamison reports. “It makes some sense of the confusion, reins in the terrifying thoughts and feelings, returns some control and hope and possibility from it all."

This unit explores some of the healing options available to therapists and the people who seek their help. We begin by exploring and evaluating *psychotherapies,* and then focus on *biomedical therapies* and preventing disorders.

▶ **Unit XIII Overview Video**

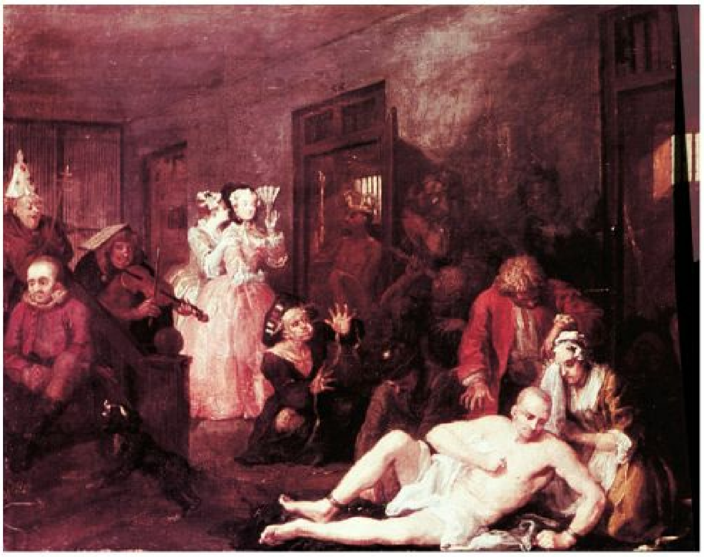
Module **70 Introduction to Therapy, and Psychodynamic and Humanistic Therapies**

LEARNING TARGETS

- 70-1 Contrast psychotherapy and the biomedical therapies.
- 70-2 Discuss the goals and techniques of psychoanalysis, and examine how they have been adapted in psychodynamic therapy.
- 70-3 Distinguish the basic themes of humanistic therapy, and describe the specific goals and techniques of Rogers' client-centered approach.

The long history of efforts to treat psychological disorders has included a bewildering mix of harsh and gentle methods. Would-be healers have cut holes in people's heads and restrained, bled, or "beat the devil" out of them. But they also have given warm baths and massages and placed people in sunny, serene environments. They have given them drugs. And they have talked with them about childhood experiences, current feelings, and maladaptive thoughts and behaviors.

Reformers Philippe Pinel (1745–1826) and Dorothea Dix (1802–1887) pushed for gentler, more humane treatments and for constructing mental hospitals. Their efforts largely paid off. Since the 1950s, the introduction of effective drug therapies and community-based treatment programs has emptied most of those hospitals.



The Granger Collection, NYC—All Rights Reserved.

The history of treatment Visitors to eighteenth-century mental hospitals paid to gawk at patients, as though they were viewing zoo animals. William Hogarth's (1697–1764) painting captured one of these visits to London's St. Mary of Bethlehem hospital (commonly called Bedlam).

Treating Psychological Disorders

70-1 How do psychotherapy and the biomedical therapies differ?

Modern Western therapies can be classified into two main categories.

- In **psychotherapy**, a trained therapist uses psychological techniques to assist someone seeking either to overcome difficulties or to achieve personal growth. The therapist may explore a client's early relationships, encourage the client to adopt new ways of thinking, or coach the client in replacing old behaviors with new ones.

psychotherapy

treatment involving psychological techniques; consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth.

- **Biomedical therapy** offers medications and other biological treatments. For example, a person with severe depression may receive antidepressants, electroconvulsive shock therapy (ECT), or deep-brain stimulation.

biomedical therapy

prescribed medications or procedures that act directly on the person's physiology.

The care provider's training and expertise, as well as the disorder itself, influence the choice of treatment. Psychotherapy and medication are often combined. Kay Redfield Jamison received psychotherapy in her meetings with her psychiatrist, and she took medications to control her wild mood swings.

Let's look first at some influential psychotherapy options for those treated with "talk therapies." Each is built on one or more of psychology's major theories: psychodynamic, humanistic, behavioral, and cognitive.

Most of these techniques can be used one-on-one or in groups. Some therapists combine techniques. Indeed, many psychotherapists describe their approach as **eclectic**, using a blend of therapies. We'll explore psychodynamic and humanistic therapies in this module, and behavior, cognitive, and group therapies in Module 71.

eclectic approach

an approach to psychotherapy that uses techniques from various forms of therapy.

AP® EXAM TIP

Most of the treatments discussed in this unit come from the perspectives you've been learning about since Unit I (Psychology's History and Approaches). As you reach each major section—like the upcoming one on psychoanalytic and psychodynamic therapy—try to anticipate how someone from that perspective would approach therapy (for example, "What would Freud do?"). This should help you organize and retain the information as you read.

Psychoanalysis and Psychodynamic Therapies

70-2 What are the goals and techniques of psychoanalysis, and how have they been adapted in psychodynamic therapy?

The first major psychological therapy was Sigmund Freud’s **psychoanalysis**. Although few clinicians today practice therapy as Freud did, his work deserves discussion. It helped form the foundation for treating psychological disorders, and it continues to influence modern therapists working from the *psychodynamic* perspective.

psychoanalysis

Sigmund Freud’s therapeutic technique. Freud believed the patient’s free associations, resistances, dreams, and transferences—and the therapist’s interpretations of them—released previously repressed feelings, allowing the patient to gain self-insight.

AP® EXAM TIP

As you read, think about the various disorders previously studied and consider how a particular form of therapy might be most effective in treating that disorder.

The Goals of Psychoanalysis

Freud believed that in therapy, people could achieve healthier, less anxious living by releasing the energy they had previously devoted to id-ego-superego conflicts (see Module 55). Freud assumed that we do not fully know ourselves. He believed that there are threatening things we *repress*—things we do not want to know, so we disavow or deny them. Psychoanalysis was Freud’s method of helping people to bring these repressed feelings into conscious awareness. By helping them reclaim their unconscious thoughts and feelings, and by giving them *insight* into the origins of their disorders, the therapist *(analyst)* could help them reduce growth-impeding inner conflicts.

The Techniques of Psychoanalysis

Psychoanalytic theory emphasizes the power of childhood experiences to mold the adult. Thus, psychoanalysis is historical reconstruction. It aims to unearth the past in the hope of loosening its bonds on the present. After discarding hypnosis as an unreliable excavator, Freud turned to *free association.*

Imagine yourself as a patient using free association. You begin by relaxing, perhaps by lying on a couch. The psychoanalyst, who sits out of your line of vision, asks you to say aloud whatever comes to mind. At one moment, you're relating a childhood memory. At another, you're describing a dream or recent experience. It sounds easy, but soon you notice how often you edit your thoughts as you speak. You pause for a second before uttering an embarrassing thought. You omit what seems trivial, irrelevant, or shameful. Sometimes your mind goes blank or you clutch up, unable to remember important details. You may joke or change the subject to something less threatening.

To the analyst, these mental blocks indicate **resistance**. They hint that anxiety lurks and you are defending against sensitive material. The analyst will note your resistance and then provide insight into its meaning. If offered at the right moment, this **interpretation**—of, say, your not wanting to talk about your mother or call, text, or message her—may illuminate the underlying wishes, feelings, and conflicts you are avoiding. The analyst may also offer an explanation of how this resistance fits with other pieces of your psychological puzzle, including those based on analysis of your dream content.

resistance

in psychoanalysis, the blocking from consciousness of anxiety-laden material.

interpretation

in psychoanalysis, the analyst’s noting supposed dream meanings, resistances, and other significant behaviors and events in order to promote insight.

Over many such sessions, your relationship patterns surface in your interaction with your therapist. You may find yourself experiencing strong positive or negative feelings for your analyst. The analyst may suggest you are **transferring** feelings, such as dependency or mingled love and anger, that you experienced in earlier relationships with family members or other important people. By exposing such feelings, you may gain insight into your current relationships.

transference

in psychoanalysis, the patient’s transfer to the analyst of emotions linked with other relationships (such as love or hatred for a parent).

Relatively few North American therapists now offer traditional psychoanalysis. Much of its underlying theory is not supported by scientific research (Module 56). Analysts’ interpretations cannot be proven or disproven. And psychoanalysis takes considerable time and money, often years of several sessions per week. Some of these problems have been addressed in the modern *psychodynamic perspective* that has evolved from psychoanalysis.

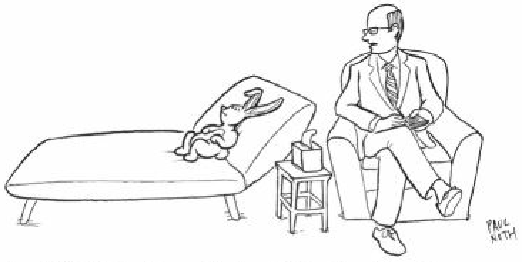
> “*I haven’t seen my analyst in 200 years. He was a strict Freudian. If I’d been going all this time, I’d probably almost be cured by now.*”
>
> *Woody Allen, after awakening from suspended animation in the movie* Sleeper

Psychodynamic Therapy

Although influenced by Freud’s ideas, **psychodynamic therapists** don’t talk much about id-ego-superego conflicts. Instead they try to help people understand their current symptoms by focusing on important relationships, including childhood experiences and the therapist-client relationship. “We can have loving feelings and hateful feelings toward the same person,” noted psychodynamic therapist Jonathan Shedler (2009), and “we can desire something and also fear it.” Client-therapist meetings take place once or twice a week (rather than several times weekly) and often for only a few weeks or months. Rather than lying on a couch, out of the therapist’s line of vision, clients meet with their therapist face-to-face and gain perspective by exploring defended-against thoughts and feelings.

psychodynamic therapy

therapy deriving from the psychoanalytic tradition; views individuals as responding to unconscious forces and childhood experiences, and seeks to enhance self-insight.



Paul Noth/The New Yorker Collection/The Cartoon Bank

“I’m more interested in hearing about the eggs you’re hiding from yourself.”

Therapist David Shapiro (1999, p. 8) illustrated this with the case of a young man who had told women that he loved them, when he knew that he didn’t. The client’s explanation: They expected it, so he said it. But with his wife, who wished he would say that he loved her, he found he *couldn’t* do that—“I don’t know why, but I can’t.”

Therapist: Do you mean, then, that if you could, you would like to?

Patient: Well, I don’t know. . . . Maybe I can’t say it because I’m not sure it’s true. Maybe I don’t love her.

Further interactions revealed that the client could not express real love because it would feel “mushy” and “soft” and therefore unmanly. He was “in conflict with himself, and . . . cut off from the nature of that conflict.” Shapiro noted that with such patients, who are estranged from themselves, therapists using psychodynamic techniques “are in a position to introduce them to themselves. We can restore their awareness of their own wishes and feelings, and their awareness, as well, of their reactions against those wishes and feelings.”

Exploring past relationship troubles may help clients understand the origin of their current difficulties. Shedler (2010a) recalled “Jeffrey’s” complaints of difficulty getting along with his colleagues and wife, who saw him as hypercritical. Jeffrey then “began responding to me as if I were an unpredictable, angry adversary.” Shedler seized this opportunity to help Jeffrey recognize the relationship pattern and its roots in the attacks and humiliation he had experienced from his alcohol-abusing father. Jeffrey was then able to work through and let go of this defensive style of responding to people. Thus, without embracing all of Freud’s theory, psychodynamic therapists aim to help people gain insight into unconscious dynamics that arise from their life experience.

Humanistic Therapies

70-3 What are the basic themes of humanistic therapy? What are the specific goals and techniques of Rogers' client-centered approach?

The *humanistic* perspective (Module 57) emphasizes people's innate potential for self-fulfillment. Not surprisingly, humanistic therapies attempt to reduce the inner conflicts that interfere with natural development and growth. To achieve this goal, humanistic therapists try to give clients new insights. Indeed, because they share this goal, the psychodynamic and humanistic therapies are often referred to as **insight therapies**. But humanistic therapies differ from psychodynamic therapies in many other ways:

insight therapies
therapies that aim to improve psychological functioning by increasing a person's awareness of underlying motives and defenses.

- *Humanistic therapists aim to boost people's self-fulfillment by helping them grow in self-awareness and self-acceptance.*
- *Promoting this growth, not curing illness, is the therapy focus.* Thus, those in therapy have become "clients" or just "persons" rather than "patients" (a change many other therapists adopted).
- *The path to growth is taking immediate responsibility for one's feelings and actions, rather than uncovering hidden determinants.*
- *Conscious thoughts are more important than the unconscious.*
- *The present and future are more important than the past.* Therapy thus focuses on exploring feelings as they occur, rather than on achieving insights into the childhood origins of those feelings.

All these themes are present in the widely used humanistic technique that Carl Rogers (1902–1987) developed and called **client-centered therapy**. In this *nondirective therapy*, the client leads the discussion. The therapist listens, without judging or interpreting, and refrains from directing the client toward certain insights. Believing that most people possess the resources for growth, Rogers (1961, 1980) encouraged therapists to foster that growth by exhibiting *acceptance*, *genuineness*, and *empathy*. When therapists enable their clients to feel unconditionally accepted, drop their facades and genuinely express their true feelings, and empathically sense and reflect their clients' feelings, the clients may deepen their self-understanding and self-acceptance (Hill & Nakayama, 2000). As Rogers (1980, p. 10) explained,

client-centered therapy

a humanistic therapy, developed by Carl Rogers, in which the therapist uses techniques such as *active listening* within an accepting, genuine, empathic environment to facilitate clients' growth. (Also called *person-centered therapy*.)

> Hearing has consequences. When I truly hear a person and the meanings that are important to him at that moment, hearing not simply his words, but him, and when I let him know that I have heard his own private personal meanings, many things happen. There is first of all a grateful look. He feels released. He wants to tell me more about his world. He surges forth in a new sense of freedom. He becomes more open to the process of change.
>
> I have often noticed that the more deeply I hear the meanings of the person, the more there is that happens. Almost always, when a person realizes he has been deeply heard, his eyes moisten. I think in some real sense he is weeping for joy. It is as though he were saying, "Thank God, somebody heard me. Someone knows what it's like to be me."

AP® EXAM TIP

You can remember *A*cceptance, *G*enuineness, and *E*mpathy as “AGE.”

> “*We have two ears and one mouth that we may listen the more and talk the less.*”
>
> *Zeno, 335–263* B.C.E., Diogenes Laertius

To Rogers, “hearing” was **active listening**. The therapist echoes, restates, and seeks clarification of what the person expresses (verbally or nonverbally) and acknowledges those expressed feelings. Active listening is now an accepted part of counseling practices in many schools, colleges, and clinics. Counselors listen attentively. They interrupt only to restate and confirm feelings, to accept what is being expressed, or to seek clarification. In the following brief excerpt, note how Rogers tried to provide a psychological mirror that would help the client see himself more clearly.

active listening

empathic listening in which the listener echoes, restates, and clarifies. A feature of Rogers’ client-centered therapy.

Michael Rougier/Getty Images

Active listening Carl Rogers (right) empathized with a client during this group therapy session.

> **Rogers:** Feeling that now, hm? That you’re just no good to yourself, no good to anybody. Never will be any good to anybody. Just that you’re completely worthless, huh?—Those really are lousy feelings. Just feel that you’re no good at all, hm?
>
> **Client:** Yeah. *(Muttering in low, discouraged voice)* That’s what this guy I went to town with just the other day told me.
>
> **Rogers:** This guy that you went to town with really told you that you were no good? Is that what you’re saying? Did I get that right?
>
> **Client:** M-hm.
>
> **Rogers:** I guess the meaning of that if I get it right is that here’s somebody that—meant something to you and what does he think of you? Why, he’s told you that he thinks you’re no good at all. And that just really knocks the props out from under you. *(Client weeps quietly.)* It just brings the tears. *(Silence of 20 seconds)*
>
> **Client:** *(Rather defiantly)* I don’t care though.
>
> **Rogers:** You tell yourself you don’t care at all, but somehow I guess some part of you cares because some part of you weeps over it.
>
> (*Meador & Rogers, 1984, p. 167*)

Can a therapist be a perfect mirror, without selecting and interpreting what is reflected? Rogers conceded that one cannot be *totally* nondirective. Nevertheless, he said, the therapist’s most important contribution is to accept and understand the client. Given a nonjudgmental, grace-filled environment that provides **unconditional positive regard**, people may accept even their worst traits and feel valued and whole.

unconditional positive regard

a caring, accepting, nonjudgmental attitude, which Carl Rogers believed would help clients develop self-awareness and self-acceptance.

How can we improve communication in our own relationships by listening more actively? Three Rogers-inspired hints may help:

1. ***Paraphrase.*** Check your understanding by summarizing the person’s words out loud, in your own words.
2. ***Invite clarification***. “What might be an example of that?” may encourage the person to say more.
3. ***Reflect feelings***. “It sounds frustrating” might mirror what you’re sensing from the person’s body language and intensity.

Check Your Understanding

Ask Yourself

- Think of your closest friends. Do they tend to express more empathy than those you don’t feel as close to? How have your own active-listening skills changed as you’ve gotten older?

Test Yourself

- In psychoanalysis, when patients experience strong feelings for their therapist, this is called ______________. Patients are said to demonstrate anxiety when they put up mental blocks around sensitive memories, indicating ______________. The therapist will attempt to provide insight into the underlying anxiety by offering a(n) ______________ of the mental blocks.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 70 REVIEW

70-1 How do psychotherapy and the biomedical therapies differ?

- *Psychotherapy* is treatment involving psychological techniques; it consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth.
- The major psychotherapies derive from psychology's psychodynamic, humanistic, behavioral, and cognitive perspectives.
- An *eclectic approach* combines techniques from various forms of psychotherapy.
- *Biomedical therapy* treats psychological disorders with medications or procedures that act directly on a patient's physiology.

70-2 What are the goals and techniques of psychoanalysis, and how have they been adapted in psychodynamic therapy?

- Through *psychoanalysis*, Sigmund Freud tried to give people self-insight and relief from their disorders by bringing anxiety-laden feelings and thoughts into conscious awareness.
    - Techniques included using free association and *interpretation* of instances of *resistance* and *transference*.
- Contemporary *psychodynamic therapy* has been influenced by traditional psychoanalysis but is briefer, less expensive, and more focused on helping the client find relief from current symptoms.
    - Therapists help clients understand themes that run through past and current relationships.

70-3 What are the basic themes of humanistic therapy? What are the specific goals and techniques of Rogers' client-centered approach?

- Both psychoanalytic and humanistic therapies are *insight therapies*—they attempt to improve functioning by increasing clients' awareness of motives and defenses.
- Humanistic therapy's goals have included helping clients grow in self-awareness and self-acceptance, promoting personal growth rather than curing illness, helping clients take responsibility for their own growth, focusing on conscious thoughts rather than unconscious motivations, and seeing the present and future as more important than the past.
- Carl Rogers' *client-centered therapy* proposed that therapists' most important contributions are to function as a psychological mirror through *active listening* and to provide a growth-fostering environment of *unconditional positive regard*, characterized by acceptance, genuineness, and empathy.

Multiple-Choice Questions

1. Dr. Carlson advises his depressed patients to discuss their childhood as well as their present lives. He also prescribes medications for them. His therapeutic style would be best described as

a. eclectic.
b. biomedical.
c. psychoanalytic.
d. transference.
e. psychodynamic.

2. What do psychodynamic therapists call the blocking of anxiety-laden material from conscious awareness?

a. Resistance
b. Interpretation
c. Transference
d. Face-to-face therapy
e. Interpersonal psychotherapy

3. Which of the following is one of the ways humanistic therapies differ from psychoanalytic therapies?

a. Humanistic therapies believe the past is more important than the present and future.
b. Humanistic therapies boost self-fulfillment by decreasing self-acceptance.
c. Humanistic therapies believe the path to growth is found by uncovering hidden determinants.
d. Humanistic therapies believe that unconscious thoughts are more important than conscious thoughts.
e. Humanistic therapies focus on promoting growth, not curing illness.

4. No matter how embarrassing her discussions with her therapist might be, Jenny recognizes that he always treats her with respect. This acceptance illustrates the client-centered technique of

a. free association.
b. active listening.
c. resistance.
d. Freudian interpretation.
e. unconditional positive regard.

Practice FRQs

1. Explain what psychoanalysis is, and then give an example of how transference and resistance would affect this therapy.

Answer

1 point: Psychoanalysis is a Freudian therapy that seeks to get patients to release repressed feelings to gain self-insight. Page 723

1 point: Transference happens when a patient shifts emotions linked with other relationships to the analyst. This can help the patient gain insight into those relationships. For example, a patient feeling angry at a sibling may transfer that to feeling angry at the therapist. Page 724

1 point: Resistance happens when a patient blocks anxiety-laden thoughts and memories from consciousness. For example, patients may find themselves avoiding discussion of their most traumatic memories.

↪ Page 723

2. Explain what client-centered therapy is, then describe the major techniques of the therapy.

(3 points)

Module **71 Behavior, Cognitive, and Group Therapies**

LEARNING TARGETS

- 71-1 Analyze how the basic assumption of behavior therapy differs from the assumptions of psychodynamic and humanistic therapies, and examine the techniques used in exposure therapies and aversive conditioning.
- 71-2 Describe the main premise of therapy based on operant conditioning principles, and contrast the views of its proponents and critics.
- 71-3 Discuss the goals and techniques of the cognitive therapies and of cognitive-behavioral therapy.
- 71-4 Discuss the aims and benefits of group and family therapies.

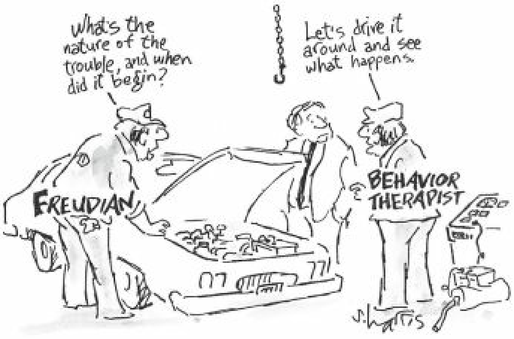
Behavior Therapies

71-1 How does the basic assumption of behavior therapy differ from the assumptions of psychodynamic and humanistic therapies? What techniques are used in exposure therapies and aversive conditioning?

The insight therapies assume that self-awareness and psychological well-being go hand in hand. Psychodynamic therapists expect people’s problems to diminish as they gain insight into their unresolved and unconscious tensions. Humanistic therapists expect problems to diminish as people get in touch with their feelings. **Behavior therapists**, however, doubt the healing power of self-awareness. Rather than delving deeply below the surface looking for inner causes, behavior therapists assume that problem behaviors *are* the problems. (You can become aware of why you are highly anxious during tests and still be anxious.) If phobias, sexual dysfunctions, or other maladaptive symptoms are learned behaviors, why not apply learning principles to replace them with new, constructive behaviors?

behavior therapy

therapy that applies learning principles to the elimination of unwanted behaviors.



What's the nature of the trouble, and when did it begin?
Let's drive it around and see what happens.
FREUDIAN
BEHAVIOR THERAPIST

Sidney Harris/ScienceCartoonsPlus.com

Classical Conditioning Techniques

One cluster of behavior therapies derives from principles developed in Ivan Pavlov's early twentieth-century conditioning experiments (Module 26). As Pavlov and others showed, we learn various behaviors and emotions through classical conditioning. If we're attacked by a dog, we may thereafter have a conditioned fear response when other dogs approach. (Our fear generalizes, and all dogs become conditioned stimuli.)

Could maladaptive symptoms be examples of conditioned responses? If so, might reconditioning be a solution? Learning theorist O. H. Mowrer thought so. He developed a successful conditioning therapy for chronic bed-wetters, using a liquid-sensitive pad connected to an alarm. If the sleeping child wets the bed pad, moisture triggers the alarm, waking the child. After a number of trials, the child associates bladder relaxation with waking. In three out of four cases, the treatment has been effective and the success boosted the child's self-image (Christophersen & Edwards, 1992; Houts et al., 1994).

Can we unlearn fear responses, such as to public speaking or flying, through new conditioning? Many people have. An example: The fear of riding in an elevator is often a learned aversion to being in a confined space. **Counterconditioning**, such as with *exposure therapy*, pairs the trigger stimulus (in this case, the enclosed space of the elevator) with a new response (relaxation) that is incompatible with fear.

counterconditioning

behavior therapy procedures that use classical conditioning to evoke new responses to stimuli that are triggering unwanted behaviors; include *exposure therapies* and *aversive conditioning.*

Exposure Therapies

Picture this scene: Behavioral psychologist Mary Cover Jones is working with 3-year-old Peter, who is petrified of rabbits and other furry objects. To rid Peter of his fear, Jones plans to associate the fear-evoking rabbit with the pleasurable, relaxed response associated with eating. As Peter begins his midafternoon snack, she introduces a caged rabbit on the other side of the huge room. Peter, eagerly munching away on his crackers and drinking his milk, hardly notices. On succeeding days, she gradually moves the rabbit closer and closer. Within two months, Peter is holding the rabbit in his lap, even stroking it while he eats. Moreover, his fear of other furry objects subsides as well, having been *countered*, or replaced, by a relaxed state that cannot coexist with fear (Fisher, 1984; Jones, 1924).

AP® EXAM TIP

Before you read the next several pages of this module, you may want to quickly review the material on classical and operant conditioning in Unit VI (Learning). Note that behavior therapists, like psychodynamic therapists, focus on childhood experiences, but in a different way. Behavior therapists acknowledge that conditioned responses may result from childhood experiences; psychodynamic therapists instead work on resolving unconscious conflicts stemming from childhood.

Unfortunately for many who might have been helped by Jones’ counterconditioning procedures, her story of Peter and the rabbit did not enter psychology’s lore when it was reported in 1924. It was more than 30 years before psychiatrist Joseph Wolpe (1958; Wolpe & Plaud, 1997) refined Jones’ counterconditioning technique into the **exposure therapies** used today. These therapies, in a variety of ways, try to change people’s reactions by repeatedly exposing them to stimuli that trigger unwanted reactions. With repeated exposure to what they normally avoid or escape, people adapt. We all experience this process in everyday life. A person moving to a new apartment may be annoyed by nearby loud traffic noise, but only for a while. The person adapts. So, too, with people who have fear reactions to specific events. Exposed repeatedly to the situation that once petrified them, with support from talk therapy, they can learn to react less anxiously (Barrera et al., 2013; Foa & McLean, 2016).

exposure therapies

behavioral techniques, such as *systematic desensitization* and *virtual reality exposure therapy*, that treat anxieties by exposing people (in imaginary or actual situations) to the things they fear and avoid.

One exposure therapy used to treat phobias is **systematic desensitization**. You cannot simultaneously be anxious and relaxed. Therefore, if you can repeatedly relax when facing anxiety-provoking stimuli, you can gradually eliminate your anxiety. The trick is to proceed gradually. If you fear public speaking, a behavior therapist might first help you construct a hierarchy of anxiety-triggering speaking situations. Yours might range from mildly anxiety-provoking situations (perhaps speaking up in a small group of friends) to panic-provoking situations (having to address a large audience).

systematic desensitization

a type of exposure therapy that associates a pleasant relaxed state with gradually increasing anxiety-triggering stimuli. Commonly used to treat phobias.

Next, the therapist would train you in *progressive relaxation.* You would learn to release tension in one muscle group after another, until you achieve a comfortable, complete relaxation. Then the therapist might ask you to imagine, with your eyes closed, a mildly anxiety-arousing situation: You are having coffee with a group of friends and are trying to decide whether to speak up. If imagining the scene causes you to feel any anxiety, you will signal by raising your finger. Seeing the signal, the therapist will instruct you to switch off the mental image and go back to deep relaxation. This imagined scene is repeatedly paired with relaxation until you feel no trace of anxiety.

The therapist will then move to the next item in your anxiety hierarchy, again using relaxation techniques to desensitize you to each imagined situation. After several sessions, you move to actual situations and practice what you had only *imagined* before, beginning with relatively easy tasks and gradually moving to more anxiety-filled ones. Conquering your anxiety in an actual situation, not just in your imagination, will increase your self-confidence (Foa & Kozak, 1986; Williams, 1987). Eventually, you may even become a confident public speaker. Often people fear not just a situation, such as public speaking, but also being incapacitated by their own fear response. As their fear subsides, so also does their fear of the fear.

> “*The only thing we have to fear is fear itself.*”
>
> *U.S. President Franklin D. Roosevelt First inaugural address, 1933*

If an anxiety-arousing situation is too expensive, difficult, or embarrassing to re-create, the therapist may recommend **virtual reality exposure therapy**. You would don a head-mounted display unit that projects a three-dimensional virtual world. The lifelike scenes, which shift as your head turns, would be tailored to your particular fear. Experimentally treated fears include flying, heights, particular animals, and public speaking (Parsons & Rizzo, 2008). If you fear flying, you could peer out a virtual window of a simulated plane, feel the engine’s vibrations, and hear it roar as the plane taxis down the runway and takes off. In controlled studies, people participating in virtual reality exposure therapy have experienced significant relief from real-life fear (Turner & Casey, 2014).

virtual reality exposure therapy

a counterconditioning technique that treats anxiety through creative electronic simulations in which people can safely face their greatest fears, such as airplane flying, spiders, or public speaking.

Left: Jack Kearse/Emory University; Right: William Britten/E+/Getty Images

Virtual reality exposure therapy Within the confines of a room, virtual reality technology exposes people to vivid simulations of feared stimuli, such as walking across a rickety bridge high off the ground.

Aversive Conditioning

An exposure therapy enables a more relaxed, positive response to an upsetting *harmless* stimulus. It helps you accept what you *should* do. **Aversive conditioning** creates a negative (aversive) response to a *harmful* stimulus (such as alcohol). It helps you to learn what you *should not* do. The aversive conditioning procedure is simple: It associates the unwanted behavior with unpleasant feelings. To treat nail biting, the therapist may suggest painting the fingernails with a nasty-tasting nail polish (Baskind, 1997). To treat alcohol use disorder, the therapist may offer the client appealing drinks laced with a drug that produces severe nausea (recall the taste-aversion experiments with rats and coyotes in Module 29). If that therapy links alcohol with violent nausea, the person's reaction to alcohol may change from positive to negative (**Figure 71.1**).

aversive conditioning

a type of counterconditioning that associates an unpleasant state (such as nausea) with an unwanted behavior (such as drinking alcohol).

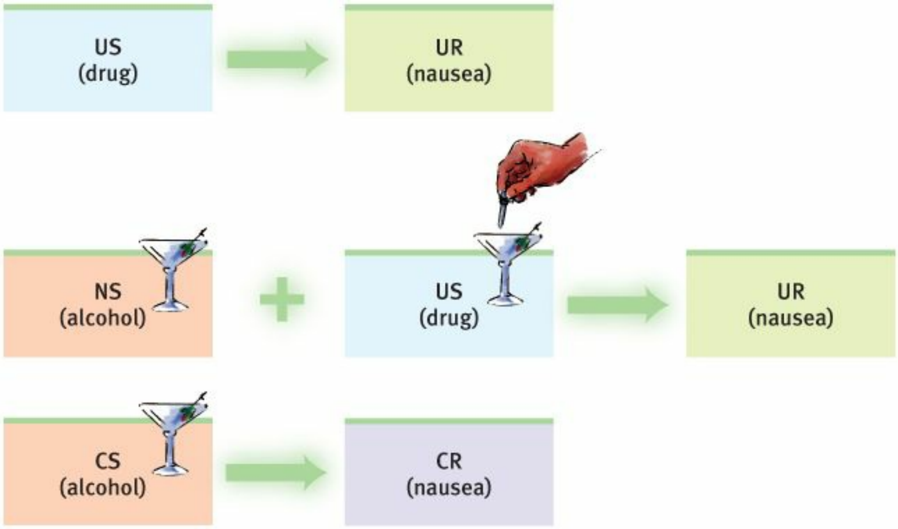


Figure 71.1
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 71.1 Aversion therapy for alcohol use disorder

After repeatedly imbibing an alcoholic drink mixed with a drug that produces severe nausea, some people with a history of alcohol use disorder develop at least a temporary conditioned aversion to alcohol. (Remember: US is unconditioned stimulus, UR is unconditioned response, NS is neutral stimulus, CS is conditioned stimulus, and CR is conditioned response.)

Flip It Video: Counterconditioning—How It Works

Taste aversion learning has been a successful alternative to killing predators in some animal protection programs (Dingfelder, 2010; Garcia & Gustavson, 1997). After being sickened by eating a contaminated sheep, wolves may avoid sheep. Does aversive conditioning also transform humans' reactions to alcohol? In the short run it may. In one classic study, 685 hospital patients with alcohol use disorder completed an aversion therapy program (Wiens & Menustik, 1983). Over the next year, they returned for several booster treatments that paired alcohol with sickness. At the end of that year, 63 percent were not drinking alcohol. But after three years, only 33 percent were alcohol free.

In therapy, as in research, cognition influences conditioning. People know that outside the therapist's office they can drink without fear of nausea. Just as animals learn to expect how often they will experience an unconditioned stimulus (Rescorla & Wagner, 1972), people can learn a probability that drinking will lead to nausea. This ability to discriminate between the therapy situation and all others can limit aversive conditioning’s effectiveness. Thus, therapists often combine aversive conditioning with other treatments.

Operant Conditioning Techniques

71-2 What is the main premise of therapy based on operant conditioning principles, and what are the views of its proponents and critics?

If you have learned to swim, you learned how to put your head under water without suffocating, how to pull your body through the water, and perhaps even how to dive safely. Operant conditioning shaped your swimming. You were reinforced for safe, effective behaviors. And you were naturally punished, as when you swallowed water, for improper swimming behaviors.

Pioneering researcher B. F. Skinner helped us understand the basic principle of operant conditioning (Modules 27 and 28): Consequences strongly influence our voluntary behaviors. Knowing this, behavior therapists can practice *behavior modification.* They reinforce behaviors they consider desirable, and they fail to reinforce—or sometimes punish—behaviors they consider undesirable.

Using operant conditioning to solve specific behavior problems has raised hopes for some seemingly hopeless cases. Children with intellectual disabilities have been taught to care for themselves. Socially withdrawn children with autism spectrum disorder (ASD) have learned to interact. People with schizophrenia have been helped to behave more rationally in their hospital ward. In such cases, therapists used positive reinforcers to *shape* behavior. In a step-by-step manner, they rewarded closer and closer approximations of the desired behavior.

In extreme cases, treatment must be intensive. One study worked with 19 withdrawn, uncommunicative 3-year-olds with ASD. For two years, 40 hours each week, the children’s parents attempted to shape their behavior (Lovaas, 1987). They positively reinforced desired behaviors and ignored or punished aggressive and self-abusive behaviors. The combination worked wonders for some children. By first grade, 9 of the 19 were functioning successfully in school and exhibiting normal intelligence. In a group of 40 comparable children not undergoing this effortful treatment, only one showed similar improvement. Later studies focused on positive reinforcement—the effective aspect of this early intensive behavioral intervention (Reichow, 2012).

Rewards used to modify behavior vary. For some people, the reinforcing power of attention or praise is sufficient. Others require concrete rewards, such as food. In institutional settings, therapists may create a **token economy**. When people display a desired behavior, such as getting out of bed, washing, dressing, eating, talking coherently, cleaning up their rooms, or playing cooperatively, they receive a token or plastic coin. Later, they can exchange a number of these tokens for rewards, such as candy, TV time, day trips, or better living quarters. Token economies have been used successfully in homes, classrooms, and detention facilities, and among people with various disabilities (Matson & Boisjoli, 2009).

token economy

an operant conditioning procedure in which people earn a token for exhibiting a desired behavior and can later exchange tokens for privileges or treats.

Behavior modification critics express two concerns:

- *How durable are the behaviors?* Will people become so dependent on extrinsic rewards that the desired behaviors will stop when reinforcers stop? Behavior modification advocates believe the behaviors will endure if therapists wean people from the tokens by shifting them toward other, real-life rewards, such as social approval. Further, they point out, the desired behaviors themselves can be rewarding. As people become more socially competent, the intrinsic satisfactions of social interaction may sustain the behaviors.

- *Is it right for one human to control another's behavior?* Those who set up token economies deprive people of something they desire and decide which behaviors to reinforce. To critics, this whole process feels too authoritarian. Advocates reply that control already exists: People's destructive behavior patterns are being maintained and perpetuated by natural reinforcers and punishers in their environments. Isn't using positive rewards to reinforce adaptive behavior more humane than institutionalizing or punishing people? Advocates also argue that the right to effective treatment and an improved life justifies temporary deprivation.

Check Your Understanding

Ask Yourself

- Have you had any experience with behavior therapy techniques in your own life, perhaps to eliminate some childhood behavior problem or to shape some good behavior? Were they effective?

Test Yourself

- What might a psychodynamic therapist say about Mowrer's therapy for bed-wetting? How might a behavior therapist defend it?
- Some maladaptive behaviors are learned. What hope does this fact provide?
- Exposure therapies and aversive conditioning are applications of _______________ conditioning. Token economies are an application of _______________ conditioning.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Cognitive Therapies

71-3 What are the goals and techniques of the cognitive therapies and of cognitive-behavioral therapy?

People with specific fears and problem behaviors may respond to behavior therapy. But how might behavior therapists modify the wide assortment of behaviors that accompany depressive disorders? Or treat people with generalized anxiety disorder, where unfocused anxiety doesn’t lend itself to a neat list of anxiety-triggering situations? The *cognitive revolution* that has profoundly changed other areas of psychology during the last half-century has influenced therapy as well (Module 2).

The **cognitive therapies** assume that our thinking colors our feelings (**Figure 71.2**). Between an event and our response lies the mind. Self-blaming and overgeneralized explanations of bad events feed depression (Module 67). Anxiety arises from an “attention bias to threat” (MacLeod & Clarke, 2015). If depressed, we may interpret a suggestion as criticism, disagreement as dislike, praise as flattery, friendliness as pity. Dwelling on such thoughts sustains negative thinking. Cognitive therapies aim to help people change their mind with new, more constructive ways of perceiving and interpreting events (Kazdin, 2015).

cognitive therapy

therapy that teaches people new, more adaptive ways of thinking; based on the assumption that thoughts intervene between events and our emotional reactions.

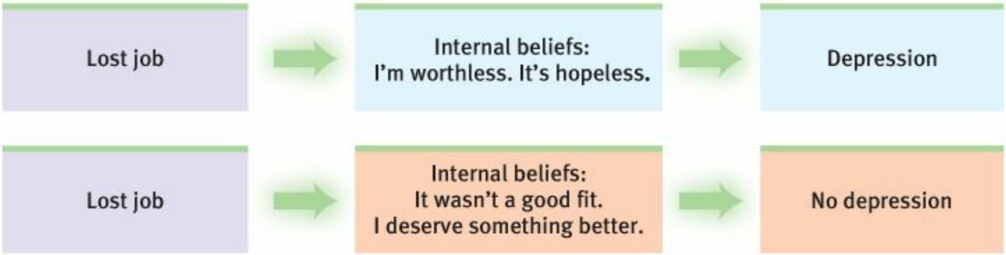

Figure 71.2

Myers/DeWall, *Myers’ Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 71.2 A cognitive perspective on psychological disorders

The person’s emotional reactions are produced not directly by the event but by the person’s thoughts in response to the event.

Rational-Emotive Behavior Therapy

According to Albert Ellis (1962, 1987, 1993), the creator of **rational-emotive behavior therapy (REBT)**, many problems arise from irrational thinking. For example, he described how therapy might challenge one client’s illogical, self-defeating assumptions (Ellis, 2011, pp. 198–199):

> [She] does not merely believe it is undesirable if her lover rejects her. She tends to believe, also, that (a) it is awful; (b) she cannot stand it; (c) she should not, must not be rejected; (d) she will never be accepted by any desirable partner; (e) she is a worthless person because one lover has rejected her; and (f) she deserves to be rejected for being so worthless. Such common covert [hidden] hypotheses are illogical, unrealistic, and destructive. . . . They can be easily elicited and demolished by any scientist worth his or her salt; and the rational-emotive therapist is exactly that: an exposing and nonsense-annihilating scientist.

rational-emotive behavior therapy (REBT)

a confrontational cognitive therapy, developed by Albert Ellis, that vigorously challenges people’s illogical, self-defeating attitudes and assumptions.

AP® EXAM TIP

Behavior therapies focus on what we do. Cognitive therapies focus on what we think. That’s a very basic distinction, but it is critically important for your understanding.

Change people's thinking by revealing the "absurdity" of their self-defeating ideas, the sharp-tongued Ellis believed, and you will change their self-defeating feelings and enable healthier behaviors.

Beck's Therapy for Depression

In the late 1960s, a woman left a party early. Things had not gone well. She felt disconnected from the other party-goers and assumed no one cared for her. A few days later, she visited therapist Aaron Beck. Rather than go down the traditional path to her childhood, Beck challenged her thinking. After she then listed a dozen people who *did* care for her, Beck realized that challenging people's automatic negative thoughts could be therapeutic. And thus was born his cognitive therapy, which assumes that changing people's thinking can change their functioning (Spiegel, 2015).

> "*Life does not consist mainly, or even largely, of facts and happenings. It consists mainly of the storm of thoughts that are forever blowing through one's mind.*"
>
> *Mark Twain, 1835–1910*

Depressed people, Beck found, often reported dreams with negative themes of loss, rejection, and abandonment. These thoughts extended into their waking thoughts, and even into therapy, as clients recalled and rehearsed their failings and worst impulses (Kelly, 2000). With cognitive therapy, Beck and his colleagues (1979) sought to reverse clients' negativity about themselves, their situations, and their futures. With this technique, gentle questioning seeks to reveal irrational thinking, and then to persuade people to remove the dark glasses through which they view life (Beck et al., 1979, pp. 145–146):

Client: I agree with the descriptions of me but I guess I don't agree that the way I think makes me depressed.

Beck: How do you understand it?

Client: I get depressed when things go wrong. Like when I fail a test.

Beck: How can failing a test make you depressed?

Client: Well, if I fail I'll never get into law school.

Beck: So failing the test means a lot to you. But if failing a test could drive people into clinical depression, wouldn't you expect everyone who failed the test to have a depression? . . . Did everyone who failed get depressed enough to require treatment?

Client: No, but it depends on how important the test was to the person.

Beck: Right, and who decides the importance?

Client: I do.

Beck: And so, what we have to examine is your way of viewing the test (or the way that you think about the test) and how it affects your chances of getting into law school. Do you agree?

Client: Right.

Beck: Do you agree that the way you interpret the results of the test will affect you? You might feel depressed, you might have trouble sleeping, not feel like eating, and you might even wonder if you should drop out of the course.

Client: I have been thinking that I wasn't going to make it. Yes, I agree.

Beck: Now what did failing mean?

Client: *(tearful)* That I couldn't get into law school.

Beck: And what does that mean to you?

Client: That I'm just not smart enough.

Beck: Anything else?

Client: That I can never be happy.

Beck: And how do these thoughts make you feel?

Client: Very unhappy.

Beck: So it is the meaning of failing a test that makes you very unhappy. In fact, believing that you can never be happy is a powerful factor in producing unhappiness. So, you get yourself into a trap—by definition, failure to get into law school equals "I can never be happy."

We often think in words. Therefore, getting people to change what they say to themselves is an effective way to change their thinking. Perhaps you can identify with the anxious students who, before a test, make matters worse with self-defeating thoughts: "This test's probably going to be impossible. Everyone seems so relaxed and confident. I wish I were better prepared. I'm so nervous I'll forget everything." Psychologists call this sort of relentless, overgeneralized, self-blaming behavior *catastrophizing.*

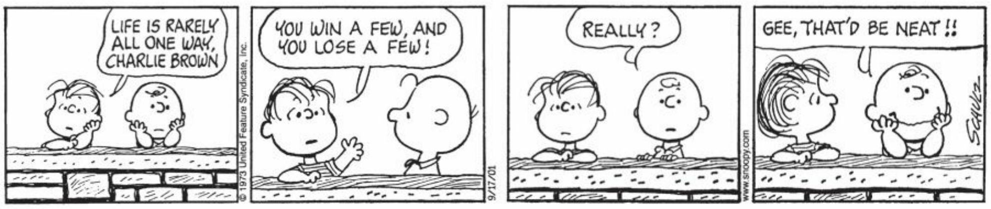
To change such negative self-talk, therapists have offered *stress inoculation training:* teaching people to restructure their thinking in stressful situations (Meichenbaum, 1977, 1985). Sometimes it may be enough simply to say more positive things to oneself: "Relax. The test may be hard, but it will be hard for everyone else, too. I studied harder than most people. Besides, I don't need a perfect score to get a good grade." After learning to "talk back" to negative thoughts, depression-prone children, teens, and college students have shown a greatly reduced rate of future depression (Reivich et al., 2013; Seligman et al., 2009). To a large extent, it *is* the thought that counts. For a sampling of commonly used cognitive therapy techniques, see **Table 71.1**.)

TABLE 71.1 Selected Cognitive Therapy Techniques

Aim of Technique	Technique	Therapists' Directives
Reveal beliefs	Question your interpretations	Explore your beliefs, revealing faulty assumptions such as "I need to be liked by everyone."

	Rank thoughts and emotions	Gain perspective by ranking your thoughts and emotions from mildly to extremely upsetting.
Test beliefs	Examine consequences	Explore difficult situations, assessing possible consequences and challenging faulty reasoning.
	Decatastrophize thinking	Work through the actual worst-case consequences of the situation you face (it is often not as bad as imagined). Then determine how to cope with the real situation you face.
Change beliefs	Take appropriate responsibility	Challenge total self-blame and negative thinking, noting aspects for which you may be truly responsible, as well as aspects that aren’t your responsibility.
	Resist extremes	Develop new ways of thinking and feeling to replace maladaptive habits. For example, change from thinking “I am a total failure” to “I got a failing grade on that paper, and I can make these changes to succeed next time.”

PEANUTS



LIFE IS RARELY ALL ONE WAY, CHARLIE BROWN
YOU WIN A FEW, AND YOU LOSE A FEW!
REALLY?
GEE, THAT'D BE NEAT!!
SCHULZ

Drawing by Charles Schultz; ©1956. Reprinted by permission of United Features Syndicate.

It’s not just depressed people who can benefit from positive self-talk. We all talk to ourselves (thinking “I wish I hadn’t said that” can protect us from repeating the blunder). The findings of nearly three dozen sport psychology studies show that self-talk interventions can enhance the learning of athletic skills (Hatzigeorgiadis et al., 2011). For example, novice basketball players may be trained to think “focus” and “follow through,” swimmers to think “high elbow,” and tennis players to think “look at the ball.” People anxious about public speaking have grown in confidence if asked to recall a speaking success, and then to “Explain

WHY you were able to achieve such a successful performance” (Zunick et al., 2015).

Cognitive-Behavioral Therapy

“The trouble with most therapy,” said Ellis, “is that it helps you to feel better. But you don’t get better. You have to back it up with action, action, action.” **Cognitive-behavioral therapy (CBT)** takes a combined approach to depression and other disorders. This widely practiced *integrative* therapy aims to alter not only the way people *think* but also the way they *act*. Like other cognitive therapies, CBT seeks to make people aware of their irrational negative thinking and to replace it with new ways of thinking. And like other behavior therapies, it trains people to *practice* the more positive approach in everyday settings.

cognitive-behavioral therapy (CBT)

a popular integrative therapy that combines cognitive therapy (changing self-defeating thinking) with behavior therapy (changing behavior).

Cognitive therapy for eating disorders aided by journaling Cognitive therapists guide people toward new ways of explaining their good and bad experiences. By recording positive events and how she has enabled them, this woman may become more mindful of her self-control and more optimistic.

Anxiety, depressive disorders, and bipolar disorder share a common problem: emotion regulation (Aldao & Nolen-Hoeksema, 2010; Szkodny et al., 2014). An effective CBT program for these emotional disorders trains people both to replace their catastrophizing thinking with more realistic appraisals, and, as homework, to practice behaviors that are incompatible with their problem (Kazantzis et al., 2010a,b; Moses & Barlow, 2006). A person might keep a log of daily situations associated with negative and positive emotions, and engage more in activities that lead to feeling good. Those who fear social situations might learn to restrain the negative thoughts surrounding their social anxiety and practice approaching people.

CBT effectively treats people with obsessive-compulsive disorder (Öst et al., 2015). In one classic study, people learned to prevent their compulsive behaviors by relabeling their obsessive thoughts (Schwartz et al., 1996). Feeling the urge to wash their hands again, they would tell themselves, “I’m having a compulsive urge.” They would explain to themselves that the hand-washing urge was a result of their brain’s abnormal activity, which they had previously viewed in PET scans. Then, instead of giving in, they would spend 15 minutes in an enjoyable, alternative behavior—practicing an instrument, taking a walk, gardening. This helped “unstick” the brain by shifting attention and engaging other brain areas. For two or three months, the weekly therapy sessions continued, with relabeling and refocusing practice at home. By the study’s end, most participants’ symptoms had diminished and their PET scans revealed normalized brain activity. Many other studies confirm CBT’s effectiveness for treating anxiety, depression, and eating disorders (Cristea et al., 2015; Milrod et al., 2015; Turner et al., 2016). Even online CBT quizzes and exercises—therapy without a face-to-face therapist—have helped alleviate insomnia, depression, and anxiety (Andersson, 2016; Christensen et al., 2016; Kampmann et al., 2016; Vigerland et al., 2016).

A newer CBT variation, *dialectical behavior therapy (DBT)*, helps change harmful and even suicidal behavior patterns (Linehan et al., 2015; Mehlum et al., 2016; Valentine et al., 2015). *Dialectical* means “opposing,” and this therapy attempts to make peace between two opposing forces—acceptance and change. Therapists create an accepting and encouraging environment, helping clients feel they have an ally who will offer them constructive feedback and guidance. In individual sessions, clients learn new ways of thinking that help them tolerate distress and regulate their emotions. They also receive training in social skills and in mindfulness meditation, which helps alleviate depression (Gu et al., 2015; Kuyken et al., 2016). Group training sessions offer additional opportunities to practice new skills in a social context, with further practice as homework.

Group and Family Therapies

71-4 What are the aims and benefits of group and family therapies?

Group Therapy

Except for traditional psychoanalysis, most therapies may also occur in small groups. **Group therapy** does not provide the same degree of therapist involvement with each client. However, it offers other benefits:

group therapy

therapy conducted with groups rather than individuals, providing benefits from group interaction.

- *It saves therapists' time and clients' money,* and often is no less effective than individual therapy (Burlingame et al., 2016).
- *It offers a social laboratory for exploring social behaviors and developing social skills.* Therapists frequently suggest group therapy for people experiencing frequent conflicts or whose behavior distresses others. The therapist guides people's interactions as they discuss issues and try out new behaviors.
- *It enables people to see that others share their problems.* It can be a relief to discover that others, despite their composure, experience some of the same troublesome feelings and behaviors (Ooi et al., 2016).
- *It provides feedback as clients try out new ways of behaving.* Hearing that you look poised, even though you feel anxious and self-conscious, can be very reassuring.

Family Therapy

One special type of group interaction, **family therapy**, assumes that no person is an island: We live and grow in relation to others, especially our families. We struggle to differentiate ourselves from our families, but we also need to connect with them emotionally. These two opposing tendencies can create stress for both the individual and the family.

family therapy

therapy that treats people in the context of their family system. Views an individual’s unwanted behaviors as influenced by, or directed at, other family members.

John Moore/Getty Images

Family therapy This type of therapy often acts as a preventive mental health strategy and may include marriage therapy, as shown here at a retreat for military families. The therapist helps family members understand how their ways of relating to one another create problems. The treatment’s emphasis is not on changing the individuals, but on changing their relationships and interactions.

Family therapists tend to view families as systems, in which each person’s actions trigger reactions from others. A child’s rebellion, for example, affects and is affected by other family tensions. Therapists are often successful in helping family members identify their roles within the family’s social system, improve communication, and discover new ways of preventing or resolving conflicts (Hazelrigg et al., 1987; Shadish et al., 1993).

Self-Help Groups

More than 100 million Americans have belonged to small religious, interest, or support groups that meet regularly—with 9 in 10 reporting that group members “support each other emotionally” (Gallup, 1994). One analysis of online support and self-help groups reported that most focus on stigmatized or hard-to-discuss illnesses (Davison et al., 2000). AIDS patients were 250 times more likely than hypertension patients to be in support groups. People with anorexia and alcohol use disorder often join groups; those with migraines and ulcers usually do not.

FYI

With more than 2 million members worldwide, AA is said to be “the largest organization on Earth that nobody wanted to join” (Finlay, 2000).

The grandparent of support groups, Alcoholics Anonymous (AA), reports having 2.1 million members in 118,000 groups worldwide. Its famous 12-step program, emulated by many other self-help groups, asks members to admit their powerlessness, to seek help from a higher power and from one another, and (the twelfth step) to take the message to others in need of it (Galanter, 2016). Studies of 12-step programs such as AA have found that they help reduce alcohol use disorder at rates comparable to other treatment interventions (Ferri et al., 2006; Moos & Moos, 2005). In an eight-year, $27 million investigation, AA participants reduced their drinking sharply, as did those assigned to CBT or an alternative therapy (Project Match, 1997). Another study of 2300 veterans who sought treatment for alcohol use disorder found that a high level of AA involvement was followed by diminished alcohol problems (McKellar et al., 2003). The more meetings AA members attend, the greater their alcohol abstinence (Moos & Moos, 2006). Those whose personal stories include a “redemptive narrative”—who see something good as having come from their struggles—more often sustain sobriety (Dunlop & Tracy, 2013).

In an individualist age, with more and more people living alone or feeling isolated, the popularity of support groups—for the addicted, the bereaved, the divorced, or simply those seeking fellowship and growth—

may reflect a longing for community and connectedness.

* * *

For a synopsis of these modern psychotherapies, see Table 71.2.

TABLE 71.2 Comparing Modern Psychotherapies

Therapy	**Presumed Problem**	**Therapy Aim**	**Therapy Technique**
Psychodynamic	Unconscious conflicts from childhood experiences	Reduce anxiety through self-insight.	Interpret patients' memories and feelings.
Client-centered	Barriers to self-understanding and self-acceptance	Enable growth via unconditional positive regard, acceptance, genuineness, and empathy.	Listen actively and reflect clients' feelings.
Behavior	Dysfunctional behaviors	Learn adaptive behaviors; extinguish problem ones.	Use classical conditioning (via exposure or aversion therapy) or operant conditioning (as in token economies).
Cognitive	Negative, self-defeating thinking	Promote healthier thinking and self-talk.	Train people to dispute negative thoughts and attributions.
Cognitive-behavioral	Self-harmful thoughts and behaviors	Promote healthier thinking and adaptive behaviors.	Train people to counter self-harmful thoughts and to act out their new ways of thinking.
Group and family	Stressful relationships	Heal relationships.	Develop an understanding of family and other social systems, explore roles, and improve

			communication.

AP® EXAM TIP

Review Table 71.2. You’ll want to be able to compare and contrast the psychotherapies.

✓ Check Your Understanding

Ask Yourself

- What is your judgment of behavior modification techniques, such as those used in token economies? Are you a proponent or a critic of this approach?

Test Yourself

- How do the humanistic and cognitive therapies differ?
- A critical attribute of ____________ ____________, developed by Aaron Beck, focuses on the belief that changing people’s thinking can change their functioning.
- What is cognitive-behavioral therapy, and what sorts of problems does this therapy best address?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 71 REVIEW

71-1 How does the basic assumption of behavior therapy differ from the assumptions of psychodynamic and humanistic therapies? What techniques are used in exposure therapies and aversive conditioning?

- *Behavior therapies* are not insight therapies. Their goal is to apply learning principles to modify problem behaviors.
- Classical conditioning techniques, including *exposure therapies* (such as *systematic desensitization* or *virtual reality exposure therapy*) and *aversive conditioning*, attempt to change behaviors through *counterconditioning*—evoking new responses to old stimuli that trigger unwanted behaviors.

71-2 What is the main premise of therapy based on operant conditioning principles, and what are the views of its proponents and critics?

- Therapy based on operant conditioning principles uses behavior modification techniques to change unwanted behaviors through positively reinforcing desired behaviors and ignoring or punishing undesirable behaviors.
- Critics maintain that (1) techniques such as those used in *token economies* may produce behavior changes that disappear when rewards end, and (2) deciding which behaviors should change is authoritarian and unethical.
- Proponents argue that treatment with positive rewards is more humane than punishing people or institutionalizing them for undesired behaviors.

71-3 What are the goals and techniques of the cognitive therapies

and of cognitive-behavioral therapy?

- The *cognitive therapies*, such as Aaron Beck’s cognitive therapy for depression, assume that our thinking influences our feelings, and that the therapist’s role is to change clients’ self-defeating thinking by training them to perceive and interpret events in more constructive ways.
- *Rational-emotive behavior therapy (REBT)* is a confrontational cognitive therapy that actively challenges irrational beliefs.
- The widely researched and practiced *cognitive-behavioral therapy (CBT)* combines cognitive therapy and behavior therapy by helping clients regularly try out their new ways of thinking and acting in their everyday life.

71-4 What are the aims and benefits of group and family therapy?

- *Group therapy* sessions can help more people and costs less per person than individual therapy would. Clients may benefit from exploring feelings and developing social skills in a group situation, from learning that others have similar problems, and from getting feedback on new ways of behaving.
- *Family therapy* views a family as an interactive system. It attempts to help members discover the roles they play and learn to communicate more openly and directly.

Multiple-Choice Questions

1. Dr. Welle tries to help her clients by teaching them to modify the way they think when under stress or experiencing symptoms. This means that Dr. Welle engages in __________ therapy.

a. behavior
b. cognitive
c. group

d. rational-emotive behavior
e. client-centered

2. Mary Cover Jones helped a little boy named Peter overcome his fear of rabbits by gradually moving a rabbit closer to him each day while he was eating his snack. This was one of the first applications of

a. group therapy.
b. virtual reality exposure therapy.
c. aversive therapy.
d. exposure therapy.
e. cognitive therapy.

3. For every five assignments they complete, Senorita Vale gives her students one “Homework Puntos.” They can use those passes to opt out of future assignments. She is making use of a technique known as

a. family therapy.
b. systematic desensitization.
c. exposure therapy.
d. REBT.
e. a token economy.

4. Jayne has been diagnosed with depression. Her therapist suggested that she get out and interact with her friends more, and that she not allow herself to worry about whether her friends want to be around her. Jayne’s therapist is using what type of approach to treat her depression?

a. Cognitive-behavioral therapy
b. Group therapy
c. Rational-emotive behavior therapy
d. Behavior modification
e. Systematic desensitization

Practice FRQs

1. Alberto has an intense fear of dogs.

- Explain how systematic desensitization could be used as a treatment for this phobia.
- Describe how this therapy would be *counterconditioning* Alberto.

Answer

1 point: With systematic desensitization, a therapist would train Alberto in the use of relaxation techniques while gradually exposing him to the feared stimulus—dogs. Alberto would learn to tolerate situations involving closer and closer proximity to, and finally interaction with, a dog—until he no longer exhibits a fear response to dogs. Page 730

1 point: Therapists using counterconditioning assume that if a phobia has been learned, then it can be unlearned, and that we can’t simultaneously experience anxiety and relaxation. So, if Alberto learns to relax around dogs, then he will no longer experience fear in their presence. The relaxation response will *counter* the fear response. Page 730

2. Explain a possible treatment of obsessive-compulsive disorder from each of the following types of therapy:

- Group therapy
- Cognitive therapy
- Behavioral therapy

(3 points)

Module 72 Evaluating Psychotherapies

LEARNING TARGETS

- 72-1 Analyze whether psychotherapy works and discuss how we can make this judgment.
- 72-2 Discuss which psychotherapies are more effective for specific disorders.
- 72-3 Discuss how alternative therapies fare under scientific scrutiny.
- 72-4 Distinguish the three elements shared by all forms of psychotherapy.
- 72-5 Describe how culture and values influence the therapist-client relationship.
- 72-6 Discuss what a person should look for when selecting a psychotherapist.

Many people presume psychotherapy’s effectiveness. “Seek counseling” or “Ask your mate to find a therapist,” advice columnists often urge. Before 1950, psychiatrists were the primary providers of mental health care. Today’s providers include clinical and counseling psychologists; clinical social workers; pastoral, marital, abuse, and school counselors; and psychiatric nurses. With such an enormous outlay of time as well as money and effort, it is important to ask: Are the millions of people worldwide justified in placing their hopes in psychotherapy?

Is Psychotherapy Effective?

72-1 Does psychotherapy work? How can we know?

The question, though simply put, is not simply answered. If an infection quickly clears, we may assume an antibiotic has been effective. But how can we assess psychotherapy’s effectiveness? By how we feel about our progress? By how our therapist feels about it? By how our friends and family feel about it? By how our behavior has changed?

Clients’ Perceptions

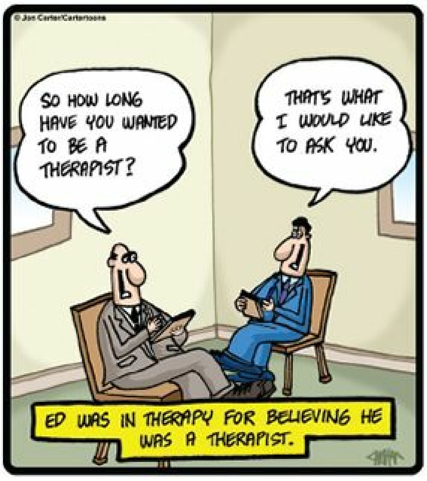
If clients’ testimonials were the only measuring stick, we could strongly affirm psychotherapy’s effectiveness. Consider the 2900 *Consumer Reports* readers who related their experiences with mental health professionals (1995; Kotkin et al., 1996; Seligman, 1995). How many were at least “fairly well satisfied”? Almost 90 percent (as was Kay Redfield Jamison, as we saw at this unit’s beginning). Among those who recalled feeling *fair* or *very poor* when beginning therapy, 9 in 10 now were feeling *very good*, *good*, or at least *so-so*. We have their word for it—and who should know better?

We should not dismiss these testimonials. But critics note reasons for skepticism:

- ***People often enter therapy in crisis.*** When, with the normal ebb and flow of events, the crisis passes, people may attribute their improvement to the therapy. Depressed people often get better no matter what they do.
- ***Clients believe that treatment will be effective.*** The *placebo effect* is the healing power of positive expectations.
- ***Clients generally speak kindly of their therapists.*** Even if the problems remain, clients “work hard to find something positive to say. The therapist had been very understanding, the client had gained a new perspective, he learned to communicate better, his mind was eased, anything at all so as not to have to say treatment was a failure”

(Zilbergeld, 1983, p. 117).

- ***Clients want to believe the therapy was worth the effort.*** To admit investing time and money in something ineffective is like admitting to having one’s car serviced repeatedly by a mechanic who never fixes it.



SO HOW LONG HAVE YOU WANTED TO BE A THERAPIST?
THAT'S WHAT I WOULD LIKE TO ASK YOU.
ED WAS IN THERAPY FOR BELIEVING HE WAS A THERAPIST.

Jon Carter/Cartoonstock

As earlier units document, we are prone to selective and biased recall and to making judgments that confirm our beliefs. Psychologists call this *effort justification*. Consider the testimonials gathered in a massive experiment with over 500 Massachusetts boys, aged 5 to 13 years, many of whom seemed bound for delinquency. By the toss of a coin, half the boys were assigned to a 5-year treatment program. The treated boys were visited by counselors twice a month. They participated in community programs, and they received academic tutoring, medical attention, and family assistance as needed. Some 30 years later, Joan McCord (1978, 1979) located 485 participants, sent them questionnaires, and checked public records from courts, mental hospitals, and other sources. Was the treatment successful?

Client testimonials were glowing. Some men noted that, had it not been for their counselors, “I would probably be in jail,” “My life would have gone the other way,” or “I think I would have ended up in a life of crime.” Court records offered apparent support: Even among the “difficult” boys in the treatment group, 66 percent had no official juvenile crime record.

But recall psychology’s most powerful tool for sorting reality from wishful thinking: the *control group*. For every boy in the treatment group, there was a similar boy in a control group, receiving no counseling. Of these untreated men, *70 percent* had no juvenile record. On several other measures, such as a record of having committed a second crime, alcohol use disorder, death rate, and job satisfaction, the untreated men exhibited slightly *fewer* problems. The glowing testimonials of those treated had been unintentionally deceiving.

Clinicians' Perceptions

If clinicians' perceptions were proof of therapy's effectiveness, we would have even more reason to celebrate. Case studies of successful treatment abound. The problem is that clients justify entering psychotherapy by emphasizing their unhappiness and justify leaving by emphasizing their well-being. Therapists treasure compliments from clients as they say good-bye or later express their gratitude, but they hear little from clients who experience only temporary relief and seek out new therapists for their recurring problems. Thus, therapists are most aware of the failures of other therapists—those whose clients, having experienced only temporary relief, are now seeking a new therapist for their recurring problems. The same person, with the same recurring anxieties, depression, or marital difficulty, may be a "success" story in several therapists' files. Moreover, therapists, like the rest of us, are vulnerable to cognitive errors, such as *confirmation bias* and *illusory correlation* (Lilienfeld et al., 2015).

Outcome Research

How, then, can we objectively measure the effectiveness of psychotherapy? What *outcomes* can we expect—what types of people and problems are helped, and by what type of psychotherapy?

In search of answers, psychologists have turned to the well-traveled path of controlled research. Similar research in the 1800s transformed the field of medicine when skeptical physicians began to realize that many patients were dying despite receiving fashionable treatments (bleeding, purging), and others were getting better on their own. Sorting fact from superstition required observing patients and recording outcomes with and without a particular treatment. Typhoid fever patients, for example, often improved after being bled, convincing most physicians that the treatment worked. Then came the shock. A control group was given mere bed rest, and after five weeks of fever, 70 percent improved, showing that the bleeding was worthless (Thomas, 1992).

In the twentieth century, psychology, with its many different therapy options, faced a similar challenge. British psychologist Hans Eysenck (1952) launched a spirited debate when he summarized 24 studies of psychotherapy outcomes. He found that two-thirds of those receiving psychotherapy for disorders not involving hallucinations or delusions improved markedly. To this day, no one disputes that optimistic estimate.

Why, then, are we still debating psychotherapy’s effectiveness? Because Eysenck also reported similar improvement among *untreated* persons, such as those who were on waiting lists for treatment. With or without psychotherapy, he said, roughly two-thirds improved noticeably. Time was a great healer.

Later research revealed shortcomings in Eysenck’s analyses. His sample was small—only 24 outcome studies in 1952, compared with the hundreds available today. The best of these are *randomized clinical trials*, in which researchers randomly assign people on a waiting list to therapy or to no therapy. Later, they evaluate everyone and compare outcomes, with tests and assessments by others who don’t know whether therapy was given.

Feng Li/Getty Images

Trauma These women were mourning the tragic loss of lives and homes in the 2010 earthquake in China. Those who suffer through such trauma may benefit from counseling, though many people recover on their own or with the help of supportive relationships with family and friends. “Life itself still remains a very effective therapist,” noted psychodynamic therapist Karen Horney (*Our Inner Conflicts*, 1945).

A glimpse of psychotherapy’s overall effectiveness can then be provided by means of a **meta-analysis**, a statistical procedure that combines the conclusions of a large number of different studies. Simply said, meta-analyses give us the bottom-line result of lots of studies. Therapists welcomed the first meta-analysis of some 475 psychotherapy outcome studies (Smith et al., 1980). It showed that the average therapy client ends up better off than 80 percent of the untreated individuals on waiting lists (**Figure 72.1**). The claim is modest—by definition, about 50 percent of untreated people also are better off than the average untreated person. Nevertheless, Mary Lee Smith and her colleagues exulted that “psychotherapy benefits people of all ages as reliably as schooling educates them, medicine cures them, or business turns a profit” (p. 183).

meta-analysis

a procedure for statistically combining the results of many different research studies.

Data from Smith et al., 1980.

Figure 72.1 Treatment versus no treatment

These two normal distribution curves based on data from 475 studies show the improvement of untreated people and psychotherapy clients. The outcome for the average therapy client surpassed the outcome for 80 percent of the untreated people.

Flip It Video: Outcome Research—Applying Science to Therapy

Dozens of subsequent summaries have now examined psychotherapy's effectiveness. Their verdict echoes earlier results: *Those not undergoing therapy often improve, but those undergoing therapy are more likely to improve—and to improve more quickly and with less risk of relapse* (Kolovos et al., 2017; Weisz et al., 2017). (One qualification: Compared with studies that find no therapy benefit, those that do find a positive therapy effect are more likely to get published [Driessen et al., 2015].) Even so, many people exhibit a more stable and outgoing personality after therapy (Roberts et al., 2017). And some people experience sudden symptom reductions between their treatment sessions for depression or anxiety. Those "sudden gains" bode well for long-term improvement (Aderka et al., 2012).

Psychotherapy also can be cost-effective. Studies show that when people seek psychological treatment, their search for other medical treatment drops—by 16 percent in one digest of 91 studies (Chiles et al., 1999). Given the staggering annual cost of psychological disorders and substance abuse—including crime, accidents, lost work, and treatment—psychotherapy is a good investment, much like money spent on prenatal and well-baby care (Chisholm et al., 2016; Ising et al., 2015). Both *reduce* long-term costs. Boosting employees' psychological well-being can lower medical costs, improve work efficiency, and diminish absenteeism.

But note that the claim—that psychotherapy, *on average,* is somewhat effective—refers to no one therapy in particular. It is like reassuring lung-cancer patients that "on average," medical treatment of health problems is effective. But what distressed people—and those paying for their therapy—want to know is whether a *particular* treatment is effective for their specific problems.

Which Psychotherapies Work Best?

72-2 Are some psychotherapies more effective than others for specific disorders?

The early statistical summaries and surveys did not find that any one type of psychotherapy is generally superior (Smith & Glass, 1977, Smith et al., 1980). Later studies have similarly found little connection between clients' outcomes and their clinicians' experience, training, supervision, and licensing (Barth et al., 2013; Cuijpers, 2017; Kivlighan et al., 2015). A *Consumer Reports* survey confirmed this result. Were clients treated by a psychiatrist, psychologist, or social worker? Were they seen in a group or individual context? Did the therapist have extensive or relatively limited training and experience? It didn't matter. Clients seemed equally satisfied (Seligman, 1995).

> “*Different sores have different salves.*”
>
> *English proverb*

So, was the dodo bird in *Alice in Wonderland* right: “Everyone has won and all must have prizes”? Not quite. One general finding emerges from the studies: The more specific the problem, the greater the hope that psychotherapy might solve it (Singer, 1981; Westen & Morrison, 2001). Those who experience phobias or panic, who are unassertive, or who are frustrated by sexual performance problems can hope for improvement. Those with less-focused problems, such as depression and anxiety, usually benefit in the short term but often relapse later. There often is also an overlapping or *comorbidity* of disorders.

Nevertheless, some forms of therapy do get prizes for effectively treating *particular* problems:

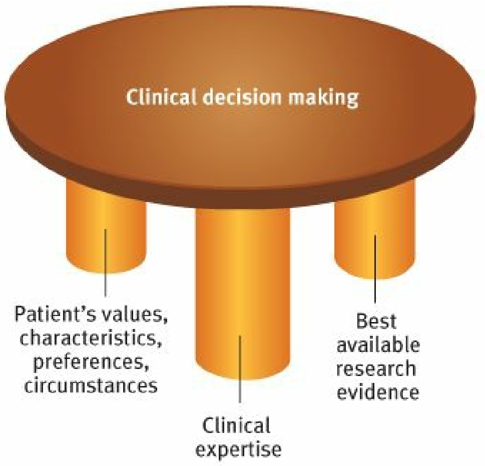
- *Cognitive and cognitive-behavioral therapies*—anxiety, posttraumatic stress disorder, insomnia, and depression (Qaseem et al., 2016; Scaini et al., 2016; Tolin, 2010).

- *Behavioral conditioning therapies*—specific behavior problems, such as bed-wetting, phobias, compulsions, marital problems, and sexual dysfunctions (Baker et al., 2008; Hunsley & DiGiulio, 2002; Shadish & Baldwin, 2005).
- *Psychodynamic therapy*—depression and anxiety (Driessen et al., 2010; Leichsenring & Rabung, 2008; Shedler, 2010b).
- *Nondirective (client-centered) counseling*—mild to moderate depression (Cuijpers et al., 2012).

The evaluation question—which therapies get prizes and which do not?—lies at the heart of what some call psychology's civil war. To what extent should science guide both clinical practice and the willingness of health care providers and insurers to pay for psychotherapy? On one side are research psychologists using scientific methods to extend the list of well-defined and validated therapies for various disorders. They decry clinicians who "give more weight to their personal experience than to science" (Baker et al., 2008). On the other side are nonscientist therapists who view their practice as more art than science: People are too complex and psychotherapy is too intuitive to describe in a manual or test in an experiment. Between these two factions stand the science-oriented clinicians calling for **evidence-based practice**, which has been endorsed by the American Psychological Association and others (2006; Lilienfeld et al., 2013). Therapists using this approach integrate the best available research with clinical expertise and with patient preferences and characteristics (**Figure 72.2**). After rigorous evaluation, clinicians apply therapies suited to their own skills and their patients' unique situations. Increasingly, insurer and government support for mental health services requires evidence-based practice.

evidence-based practice

clinical decision making that integrates the best available research with clinical expertise and patient characteristics and preferences.



Clinical decision making
Patient's values, characteristics, preferences, circumstances
Clinical expertise
Best available research evidence

Figure 72.2
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 72.2 Evidence-based clinical decision making

The ideal clinical decision making can be visualized as a three-legged stool, upheld by research evidence, clinical expertise, and knowledge of the patient.

✓ Check Your Understanding

Ask Yourself

- Based on what you've read, would you seek therapy if you were experiencing a problem? If you've already undergone therapy, does what you've learned alter your feelings about the experience?

Test Yourself

- How might the *placebo effect* bias clients' and clinicians' appraisals of the effectiveness of psychotherapies?
- Therapy is most likely to be helpful for those with problems that _______________ (are/are not) well-defined.
- What is *evidence-based practice?*

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Evaluating Alternative Therapies

72-3 How do alternative therapies fare under scientific scrutiny?

The tendency of many abnormal states of mind to return to normal, combined with the placebo effect (the healing power of mere belief in a treatment), creates fertile soil for pseudotherapies. Bolstered by anecdotes, boosted by the media, and broadcast on the Internet, alternative therapies —newer, nontraditional therapies, which often claim healing powers for various ailments—can spread like wildfire. In one national survey, 57 percent of those with a history of anxiety attacks and 54 percent of those with a history of depression had used alternative treatments, such as herbal medicine and spiritual healing (Kessler et al., 2001).

Proponents of alternative therapies often feel that their personal testimonials are evidence enough. But how well do these therapies stand up to scientific scrutiny? There is little evidence for or against most of them. Some, however, have been the subject of controlled research. No prizes—and no scientific support—go to certain alternative therapies (Arkowitz & Lilienfeld, 2006; Lilienfeld et al., 2015). We would all be wise to avoid *energy therapies* that propose to manipulate the client's invisible "energy fields," hand-guided *facilitated communication* with uncommunicative people, *recovered-memory therapies* that aim to unearth "repressed memories" of early child abuse (Module 33), and *rebirthing therapies* that reenact the supposed trauma of a client's birth.

As with medical treatments, some psychological treatments are not only ineffective but also harmful (Barlow, 2010; Castonguay et al., 2010; Dimidjian & Hollon, 2010). The National Science and Technology Council has cited the Scared Straight program (seeking to deter children and youth from crime by having them visit with adult inmates) as an example of one such well-intentioned but ineffective program. The American Psychiatric Association and British Psychological Society have warned against "conversion therapy" for those with same-sex attractions. Conversion therapies, including "reparative therapy," aim to "repair" "something that is not a mental illness and therefore does not require therapy," declared American Psychological Association president Barry Anton (2015). "There is insufficient scientific evidence that they work, and they have the potential to harm the client."

Let's look more closely at two other alternative therapies. As we do, remember that sifting sense from nonsense requires the scientific attitude: being skeptical but not cynical, open to surprises but not gullible.

Eye Movement Desensitization and Reprocessing (EMDR)

EMDR (eye movement desensitization and reprocessing) is a therapy adored by thousands and dismissed by thousands more as a sham. Psychologist Francine Shapiro (1989, 2007, 2012) developed EMDR while walking in a park and observing that anxious thoughts vanished as her eyes spontaneously darted about. Back in the clinic, she had people imagine traumatic scenes while she triggered eye movements by waving her finger in front of their eyes, supposedly enabling them to unlock and reprocess previously frozen memories. Thousands of mental health professionals from more than 75 countries have since undergone training (EMDR, 2011).

Does EMDR work? Shapiro (1999, 2002) believes it does, and she cites four studies in which it worked for 84 to 100 percent of single-trauma victims. Other studies have confirmed its benefits with trauma survivors (Chen et al., 2015). But why, wonder skeptics, would rapidly moving one's eyes while recalling traumas be therapeutic? Some argue that eye movements relax or distract patients, thus allowing memory-associated emotions to extinguish (Gunter & Bodner, 2008). (Part of therapeutic change is calling up old memories and associating them with new emotions [Lane et al., 2015].) Others believe the eye movements themselves are *not* the therapeutic ingredient (nor is watching high-speed Ping-Pong therapeutic). Trials in which people imagined traumatic scenes and tapped a finger, or just stared straight ahead while the therapist's finger wagged, have also produced therapeutic results (Devilly, 2003).

> “*Studies indicate that EMDR is just as effective with fixed eyes. If that conclusion is right, what’s useful in the therapy (chiefly behavioral desensitization) is not new, and what’s new is superfluous.*”
>
> *Harvard Mental Health Letter, 2002*

Skeptics acknowledge that EMDR does work better than doing nothing (Lilienfeld & Arkowitz, 2007). But they suspect that what is therapeutic is the combination of exposure therapy—repeatedly calling up traumatic memories and reconsolidating them in a safe and reassuring context—and perhaps some placebo effect.

Light Exposure Therapy

Have you ever found yourself oversleeping, gaining weight, and feeling lethargic, perhaps during the dark mornings and overcast days of winter? Slowing down and conserving energy during the cold, barren winters may have given our distant ancestors a survival advantage. To counteract lethargy, National Institute of Mental Health researchers in the early 1980s had an idea: Give people a timed daily dose of intense light. Sure enough, people reported they felt better.

SEASONAL FUND-RAISING

Was light exposure a bright idea, or another dim-witted example of the placebo effect? Research illuminates the issue. One study exposed some people with a seasonal pattern in their depression symptoms to 90 minutes of bright light and others to a sham placebo treatment—a hissing “negative ion generator" about which the staff expressed similar enthusiasm (but which was actually just producing white noise). After four weeks, 61 percent of those exposed to morning light had greatly improved, as had 50 percent of those exposed to evening light and 32 percent of those exposed to the placebo (Eastman et al., 1998).

Some studies have cast a shadow on light exposure therapy. Nevertheless, others have shown that 30 minutes of morning exposure to 10,000-lux white fluorescent light produces relief for most depressed people. Moreover, it does so as effectively as taking antidepressant drugs or undergoing cognitive-behavioral therapy (Lam et al., 2006, 2016; Rohan et al., 2007, 2015). Brain scans help explain the benefit: Light therapy sparks activity in a brain region that influences the body's arousal and hormone levels (Ishida et al., 2005).

Christine Brune

Light therapy To counteract depression, some people spend time each morning exposed to intense light that mimics natural outdoor light. Light boxes are available from health supply and lighting stores.

How Do Psychotherapies Help People?

72-4 What three elements are shared by all forms of psychotherapy?

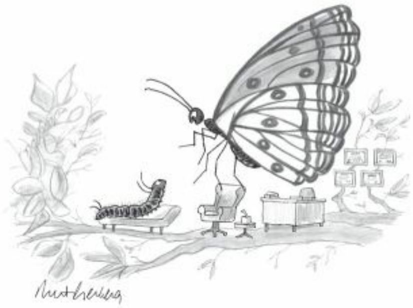
Why have studies found little correlation between therapists’ training and experience and clients’ outcomes? The answer seems to be that all psychotherapies share three basic benefits (Frank, 1982; Wampold, 2007):

- ***Hope for demoralized people*** People seeking therapy typically feel anxious, depressed, self-disapproving, and incapable of turning things around. What any psychotherapy offers is the expectation that, with commitment from the therapy seeker, things can and will get better. This belief, apart from any therapeutic technique, may improve morale, create feelings of self-efficacy, and diminish symptoms (Corrigan, 2014; Meyerhoff & Rohan, 2016).
- ***A new perspective*** Every therapy offers people a plausible explanation of their symptoms. Armed with a believable fresh perspective, they may approach life with a new attitude, open to making changes in their behaviors and their views of themselves.
- ***An empathic, trusting, caring relationship*** To say that therapy outcome is unrelated to training and experience is not to say all *therapists* are equally effective. No matter what technique they use, effective therapists are empathic. They seek to understand the client’s experience. They communicate care and concern, and they earn trust through respectful listening, reassurance, and guidance. These qualities were clear in recorded therapy sessions from 36 recognized master therapists (Goldfried et al., 1998). Some took a cognitive-behavioral approach. Others used psychodynamic principles. Regardless, the striking finding was how *similar* they were. At key moments, the empathic therapists of both persuasions would help clients evaluate themselves, link one aspect of their life with another, and gain insight into their interactions with others. The emotional bond between therapist and client—the

therapeutic alliance—helps explain why empathic, caring therapists are especially effective (Klein et al., 2003; Wampold, 2001).

David Buffington/Getty Images

A caring relationship Effective therapists form a bond of trust with their clients.



Mort Gerberg The New Yorker Collection /The Cartoon Bank

“The thing is, you have to really want to change.”

therapeutic alliance

a bond of trust and mutual understanding between a therapist and client, who work together constructively to overcome the client’s problem.

These three common elements—hope, a fresh perspective, and an empathic, caring relationship—help us understand why *paraprofessionals* (briefly trained caregivers, who may be recovered former clients) can assist many troubled people so effectively (Bryan & Arkowitz, 2015; Christensen & Jacobson, 1994). They are also part of what the growing numbers of self-help and support groups offer their members. And they are part of what traditional healers have offered (Jackson, 1992). Healers everywhere—special people to whom others disclose their suffering, whether psychiatrists, witch doctors, or shamans—have listened in order to understand and to empathize, reassure, advise, console, interpret, or explain (Torrey, 1986). Such qualities may explain why people who feel supported by close relationships—who enjoy the fellowship and friendship of caring people—have been less likely to need or seek therapy (Frank, 1982; O'Connor & Brown, 1984).

* * *

To recap, people who seek help usually improve. So do many of those who do not undergo psychotherapy, and that is a tribute to our human resourcefulness and our capacity to care for one another. Nevertheless, though the therapist's orientation and experience appear not to matter much, people who receive some psychotherapy usually improve more than those who do not. People with clear-cut, specific problems tend to improve the most.

Culture and Values in Psychotherapy

72-5 How do culture and values influence the therapist-client relationship?

All psychotherapies offer hope, and nearly all psychotherapists attempt to enhance their clients' sensitivity, openness, personal responsibility, and sense of purpose (Jensen & Bergin, 1988). But in matters of culture and values, psychotherapists differ from one another and may differ from their clients (Delaney et al., 2007; Kelly, 1990).

These differences can create a mismatch when a therapist from one culture interacts with a client from another. In North America, Europe, and Australia, for example, most psychotherapists reflect their culture's *individualism*, which often gives priority to personal desires and identity. Clients with a *collectivist* perspective, as with many from Asian cultures, may assume people will be more mindful of social and family responsibilities, harmony, and group goals. These clients may have trouble relating to therapies that require them to think only of their own well-being (Markus & Kitayama, 1991).

Cultural differences help explain some groups' reluctance to use mental health services. People living in "cultures of honor" prize being strong and tough. They may feel that seeking mental health care is an admission of weakness rather than an opportunity for growth (Brown et al., 2014). And some minority groups tend to be both reluctant to seek therapy and quick to leave it (Chen et al., 2009; Sue et al., 2009). In one experiment, Asian-American clients matched with counselors who shared their cultural values (rather than mismatched with those who did not) perceived more counselor empathy and felt a stronger alliance with the counselor (Kim et al., 2005).

Client-psychotherapist mismatches may also stem from religious values. Highly religious people may prefer and benefit from religiously similar therapists, and may have trouble forming an emotional bond with one who does not share their values (Masters, 2010; Pearce et al., 2015).

Finding a Mental Health Professional

72-6 What should a person look for when selecting a psychotherapist?

Life for everyone is marked by a mix of serenity and stress, blessing and bereavement, good moods and bad. So, when should we seek a mental health professional’s help? The American Psychological Association offers these common trouble signals:

- Feelings of hopelessness
- Deep and lasting depression
- Self-destructive behavior, such as substance abuse
- Disruptive fears
- Sudden mood shifts
- Thoughts of suicide
- Compulsive rituals, such as hand washing
- Hearing voices or seeing things that others don’t experience

In looking for a psychotherapist, you may want to have a preliminary consultation with two or three. High school counseling offices are generally good starting points and may offer some free services. You can describe problems you’re experiencing and learn about each therapist’s treatment approach. You can also ask questions about the therapist’s values, credentials (**Table 72.1**), and fees. And you can assess your own feelings about each of them. The emotional bond between therapist and client is perhaps the most important factor in effective therapy.

TABLE 72.1 Therapists and Their Training

Type	**Therapy Description**
Clinical psychologists	Most are psychologists with a Ph.D. (includes research training) or Psy.D. (focuses on therapy) supplemented by a supervised internship and, often, post-doctoral training. About half work in

	agencies and institutions, half in private practice.
Psychiatrists	Psychiatrists are physicians who specialize in the treatment of psychological disorders. Not all psychiatrists have had extensive training in psychotherapy, but as M.D.s or D.O.s they can prescribe medications. Thus, they tend to see those with the most serious problems. Many have their own private practice.
Clinical or psychiatric social workers	A two-year master of social work graduate program plus postgraduate supervision prepares some social workers to offer psychotherapy, mostly to people with everyday personal and family problems. About half have earned the National Association of Social Workers' designation of clinical social worker.
Counselors	Marriage and family counselors specialize in problems arising from family relations. Clergy provide counseling to countless people. Abuse counselors work with substance abusers and with spouse and child abusers and their victims. Mental health and other counselors may be required to have a two-year master's degree.

The American Psychological Association recognizes the importance of a strong therapeutic alliance, and it welcomes diverse therapists who can relate well to diverse clients. It accredits programs that provide training in cultural sensitivity (for example, to differing values, communication styles, and language) and that recruit underrepresented cultural groups.

Check Your Understanding

Ask Yourself

- How might your culture and values influence the sort of therapy you would welcome—or your willingness to seek therapy at all?

Test Yourself

- Those who undergo psychotherapy are _______________ (more/less) likely to show improvement than those who do not undergo psychotherapy.
- What does the evidence suggest about the efficacy of EMDR and light therapy?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 72 REVIEW

72-1 Does psychotherapy work? How can we know?

- Clients’ and therapists’ positive testimonials cannot prove that therapy is actually effective, and the placebo effect makes it difficult to judge whether improvement occurred because of the treatment.
- Using *meta-analyses* to statistically combine the results of hundreds of randomized psychotherapy outcome studies, researchers have found that those not undergoing treatment often improve, but those undergoing psychotherapy are more likely to improve more quickly and with less chance of relapse.

72-2 Are some psychotherapies more effective than others for specific disorders?

- No one type of psychotherapy is generally superior to all others. Therapy is most effective for those with clear-cut, specific problems.
- Some therapies—such as behavior conditioning for treating phobias and compulsions—are more effective for specific disorders.
- Psychodynamic therapy has helped treat depression and anxiety, and cognitive and cognitive-behavioral therapies have been effective in helping people cope with anxiety, posttraumatic stress disorder, insomnia, and depression.
- *Evidence-based practice* integrates the best available research with clinicians’ expertise and patients’ characteristics, preferences, and circumstances.

72-3 How do alternative therapies fare under scientific scrutiny?

- Controlled research has found some benefits of eye movement desensitization and reprocessing (EMDR) therapy for PTSD, though possibly for reasons unrelated to eye movements.

- Light exposure therapy does seem to help those with a seasonal pattern in their depression symptoms by activating a brain region that influences arousal and hormones.

72-4 What three elements are shared by all forms of psychotherapy?

- All psychotherapies offer new hope for demoralized people; a fresh perspective; and (if the therapist is effective) an empathic, trusting, and caring relationship.
- The emotional bond of trust and understanding between therapist and client—the *therapeutic alliance*—is an important element in effective therapy.

72-5 How do culture and values influence the therapist-client relationship?

- Therapists differ in the values that influence their goals in therapy and their views of progress. These differences may create problems if therapists and clients differ in their cultural, gender, or religious perspectives.

72-6 What should a person look for when selecting a psychotherapist?

- A person seeking therapy may want to ask about the therapist's treatment approach, values, credentials, and fees.
- An important consideration is whether the therapy seeker feels comfortable and able to establish a bond with the therapist.

Multiple-Choice Questions

1. Trevor spends 45 minutes a day in front of an intense light. It is most likely that he is being treated with

a. cognitive therapy.
b. light therapy.
c. EMDR therapy.
d. rational-emotive behavior therapy.
e. psychodynamic therapy.

2. Meta-analysis is

a. a drug study based on a small sample.
b. a treatment versus no treatment group.
c. a tendency for smaller scores to move toward the average.
d. regressing from unusual to usual.
e. a way to combine the results of many studies.

3. Which of the following is the best phrase for a bond of trust and mutual understanding between a therapist and client who are working to overcome the client's problem?

a. Therapeutic alliance
b. EMDR
c. Evidence-based practice
d. Meta-analysis
e. Outcome research

4. Knowing that you have taken AP® psychology, a friend of yours asks for your opinion on which type of psychotherapy she should consider for her anxiety. What would be your advice?

a. Psychodynamic therapy is best for anxiety.
b. Rational-emotive behavior therapy has had the best results in treating anxiety.
c. She should avoid client-centered therapy as it has been shown to have very little value.
d. Cognitive, cognitive-behavioral, and psychodynamic therapies have all demonstrated effectiveness for treating anxiety.
e. It does not matter what type of psychotherapy she chooses, because

anxiety can only be treated with medication.

Practice FRQs

1. Guillermo's physician suggested that he see a therapist for possible depression. Explain how effective each of the following might be in the treatment of his depression:

- Psychiatrist
- Clinical psychologist
- Counselor

Answer

1 point: As a medical doctor, a psychiatrist would be able to prescribe medication to Guillermo. The psychiatrist, however, may not be trained in psychotherapy, so may not fully be able to help Guillermo. ↪ Page 748

1 point: A clinical psychologist would have psychotherapy training and be able to provide effective methods, such as cognitive-behavioral therapy, to Guillermo. ↪ Page 748

1 point: A counselor would be the least helpful therapist for Guillermo. This type of therapist tends to help with family, marriage, or substance abuse issues, not depression. ↪ Page 748

2. Identify three commonly agreed-upon benefits shared by all psychotherapies.

(3 points)

Module **73 The Biomedical Therapies and Preventing Psychological Disorders**

LEARNING TARGETS

- 73-1 Examine how therapeutic lifestyle change could be considered an effective biomedical therapy, and explain how it works.
- 73-2 Describe the drug therapies, and discuss how double-blind studies help researchers evaluate a drug’s effectiveness.
- 73-3 Discuss how brain stimulation and psychosurgery are used to treat specific disorders.
- 73-4 Describe the rationale for preventive mental health programs, and evaluate the importance of developing resilience.

The Biomedical Therapies

Psychotherapy is one way to treat psychological disorders. The other is *biomedical therapy*. Biomedical treatments can change the brain's chemistry with drugs; affect its circuitry with electrical stimulation, magnetic impulses, or psychosurgery; or influence its responses with lifestyle changes.

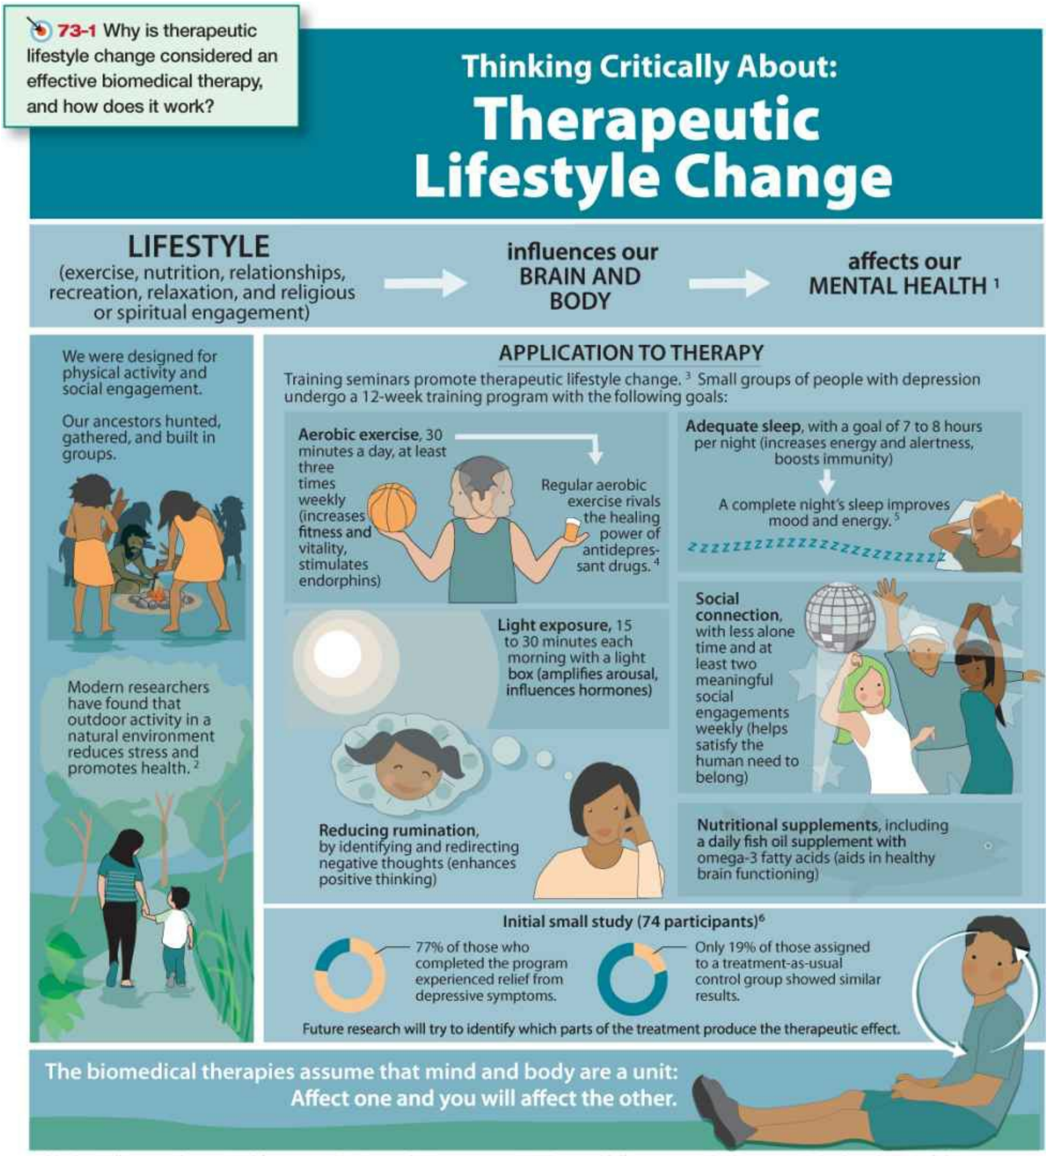
Are you surprised to find *lifestyle changes* in this list? We find it convenient to talk of separate psychological and biological influences, but everything psychological is also biological. Thus, our lifestyle—our exercise, nutrition, relationships, recreation, relaxation, and religious or spiritual engagement—affects our mental health (Schuch et al., 2016; Walsh, 2011). (See Thinking Critically About: Therapeutic Lifestyle Change.)

Every thought and feeling depends on the functioning brain. Every creative idea, every moment of joy or anger, every period of depression emerges from the electrochemical activity of the living brain. Anxiety disorders, obsessive-compulsive disorder, posttraumatic stress disorder, major depressive disorder, bipolar disorder, and schizophrenia are all biological events. Some psychologists consider even psychotherapy to be a biological treatment, because changing the way we think and behave is a brain-changing experience (Kandel, 2013). When psychotherapy relieves behaviors associated with obsessive-compulsive disorder or schizophrenia, PET scans reveal a calmer brain (Habel et al., 2010; Schwartz al., 1996). As we have seen over and over again, *a human being is an integrated biopsychosocial system.*

> “*No twisted thought without a twisted molecule.*”
>
> *Attributed to psychologist Ralph Gerard*

sturti/Getty Images

Healthier lifestyles Researchers suggest that therapeutic lifestyle change can be an effective antidote for people with depression. The changes include managing sleep time, spending more time outdoors (or with a light box), getting more exercise, and developing more social connections.



73-1 Why is therapeutic lifestyle change considered an effective biomedical therapy, and how does it work?

Thinking Critically About:

Therapeutic Lifestyle Change

LIFESTYLE (exercise, nutrition, relationships, recreation, relaxation, and religious or spiritual engagement) → **influences our BRAIN AND BODY** → **affects our MENTAL HEALTH**[1]

We were designed for physical activity and social engagement.

Our ancestors hunted, gathered, and built in groups.

Modern researchers have found that outdoor activity in a natural environment reduces stress and promotes health.[2]

APPLICATION TO THERAPY

Training seminars promote therapeutic lifestyle change.[3] Small groups of people with depression undergo a 12-week training program with the following goals:

Aerobic exercise, 30 minutes a day, at least three times weekly (increases fitness and vitality, stimulates endorphins)

Regular aerobic exercise rivals the healing power of antidepressant drugs.[4]

Adequate sleep, with a goal of 7 to 8 hours per night (increases energy and alertness, boosts immunity)

A complete night's sleep improves mood and energy.[5]

Light exposure, 15 to 30 minutes each morning with a light box (amplifies arousal, influences hormones)

Social connection, with less alone time and at least two meaningful social engagements weekly (helps satisfy the human need to belong)

Reducing rumination, by identifying and redirecting negative thoughts (enhances positive thinking)

Nutritional supplements, including a daily fish oil supplement with omega-3 fatty acids (aids in healthy brain functioning)

Initial small study (74 participants)[6]

77% of those who completed the program experienced relief from depressive symptoms.

Only 19% of those assigned to a treatment-as-usual control group showed similar results.

Future research will try to identify which parts of the treatment produce the therapeutic effect.

The biomedical therapies assume that mind and body are a unit: Affect one and you will affect the other.

Check Your Understanding

Ask Yourself

- In what ways do you think *your* lifestyle is affecting your mental health?

Test Yourself

- What are some examples of lifestyle changes we can make to enhance our mental health?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Drug Therapies

Flip It Video: How Drug Therapy Works

73-2 What are the drug therapies? How do double-blind studies help researchers evaluate a drug's effectiveness?

By far the most widely used biomedical treatments today are the drug therapies. Most drugs for anxiety and depression are prescribed by primary care providers, followed by psychiatrists and, in some states, psychologists.

Since the 1950s, discoveries in **psychopharmacology** (the study of drug effects on mind and behavior) have revolutionized the treatment of people with severe disorders, liberating hundreds of thousands from hospital confinement. Thanks to drug therapy and local community mental health programs, the resident population of U.S. state and county mental hospitals is now a small fraction of what it was in the mid-twentieth century. For some who are unable to care for themselves, however, release from hospitals has meant homelessness, not liberation.

psychopharmacology

the study of the effects of drugs on mind and behavior.

Almost any new treatment, including drug therapy, is greeted by an initial wave of enthusiasm as many people apparently improve. But that enthusiasm often diminishes on closer examination. To evaluate the effectiveness of any new drug, researchers also need to know normal recovery rates:

- How many people recover without treatment, and how quickly?
- Is recovery due to the drug or to the *placebo effect?* When patients or mental health workers expect positive results, they may see what they expect, not what really happens. Even mere exposure to advertising about a drug's supposed effectiveness can increase its effect (Kamenica

et al., 2013).

Edward Koren The New Yorker Collection/The Cartoon Bank

"Our psychopharmacologist is a genius."

To control for these influences, drug researchers give half the patients the drug, and the other half a similar-appearing placebo. Because neither the staff nor the patients know who gets which, this is called a *double-blind procedure*. The good news: In double-blind studies, several types of drugs effectively treat psychological disorders.

Antipsychotic Drugs

An accidental discovery launched a treatment revolution for people with *psychoses*. The discovery: Certain drugs, used for other medical purposes, calmed the hallucinations or delusions that are part of these patients' split from reality. First-generation **antipsychotic drugs**, such as chlorpromazine (Thorazine), dampened responsiveness to irrelevant stimuli. Thus, they provided the most help to patients experiencing positive (actively inappropriate) symptoms of schizophrenia, such as auditory hallucinations and paranoia (Lehman et al., 1998; Lenzenweger et al., 1989). (Antipsychotic drugs are not equally effective in changing negative symptoms such as apathy and withdrawal.)

antipsychotic drugs

drugs used to treat schizophrenia and other forms of severe thought disorder.

The molecules of most conventional antipsychotic drugs are similar enough to molecules of the neurotransmitter dopamine to occupy its receptor sites and block its activity. This finding reinforces the idea that an overactive dopamine system contributes to schizophrenia.

FYI

Perhaps you can guess an occasional side effect of L-dopa, a drug that raises dopamine levels for Parkinson’s patients: hallucinations.

Antipsychotics also have powerful side effects. Some produce sluggishness, tremors, and twitches similar to those of Parkinson’s disease (Kaplan & Saddock, 1989). Long-term use of antipsychotics can produce *tardive dyskinesia*, with involuntary movements of the facial muscles (such as grimacing), tongue, and limbs. Although not more effective in controlling schizophrenia symptoms, many of the newer-generation antipsychotics, such as risperidone (Risperdal) and olanzapine (Zyprexa), work best for those with severe symptoms and have fewer of these effects (Furukawa et al., 2015). These drugs may, however, increase the risk of obesity and diabetes (Buchanan et al., 2010; Tiihonen et al., 2009).

AP® EXAM TIP

The discussion of drug therapies is a great opportunity for you to review information about neurotransmitters and brain function. See Unit III (Biological Bases of Behavior) if you need to brush up on these topics.

Antipsychotics, combined with life-skills programs and family support, have given new hope to many people with schizophrenia (Guo et al., 2010). Hundreds of thousands of patients have left the wards of mental hospitals and returned to work and to near-normal lives (Leucht et al., 2003). Elyn Saks (2007), a University of Southern California law professor, knows what it means to live with schizophrenia. Thanks to her treatment, which combines an antipsychotic drug and psychotherapy, she noted, “Now I’m mostly well. I’m mostly thinking clearly. I do have episodes, but it’s not like I’m struggling all of the time to stay on the right side of the line.”

Antianxiety Drugs

Like alcohol, **antianxiety drugs**, such as Xanax or Ativan, depress central nervous system activity (and so should not be used in combination with alcohol). Some antianxiety drugs have been successfully used in combination with psychological therapy to enhance exposure therapy’s extinction of learned fears and to help relieve the symptoms of posttraumatic stress disorder and obsessive-compulsive disorder (Davis, 2005; Kushner et al., 2007).

antianxiety drugs

drugs used to control anxiety and agitation.

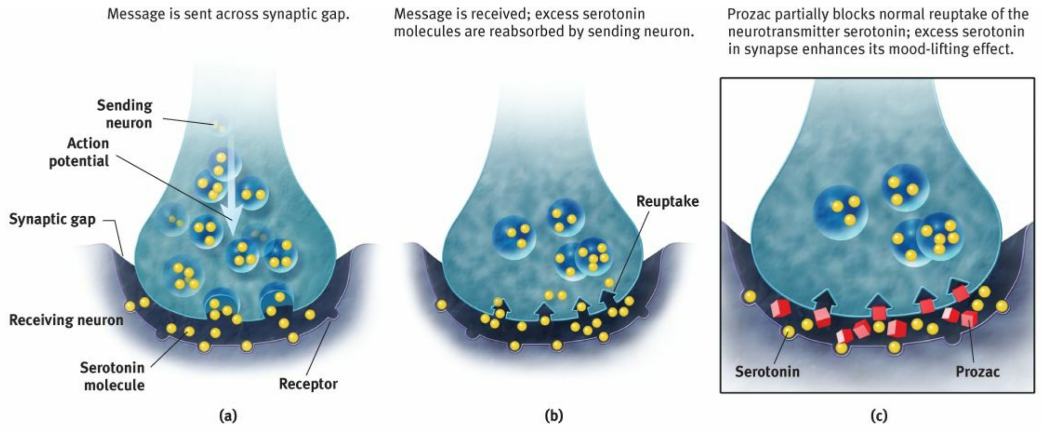
Some critics fear that antianxiety drugs may reduce symptoms without resolving underlying problems, especially when used as an ongoing treatment. “Popping a Xanax” at the first sign of tension can create a learned response: The immediate relief reinforces a person’s tendency to take drugs when anxious. Antianxiety drugs can also be addictive. Regular users who stop taking these drugs may experience increased anxiety, insomnia, and other withdrawal symptoms.

Antidepressant Drugs

The **antidepressant drugs** were named for their ability to lift people up from a state of depression, and this was their main use until recently. The label is a bit of a misnomer now that these drugs are increasingly used to treat anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder (Wetherell et al., 2013). Many work by increasing the availability of neurotransmitters, such as norepinephrine or serotonin, which elevate arousal and mood and are scarce when a person experiences feelings of depression or anxiety. The most commonly prescribed drugs in this group, including Prozac and its cousins Zoloft and Paxil, work by prolonging the time serotonin molecules remain in the brain’s synapses. They do this by partially blocking the normal reuptake process (**Figure 73.1**). Given their use in treating disorders other than depression—from anxiety to strokes—these drugs are most often called *SSRIs—selective serotonin reuptake inhibitors* (rather than antidepressants) (Kramer, 2011).

antidepressant drugs

drugs used to treat depression, anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder. (Several widely used antidepressant drugs are *selective serotonin reuptake inhibitors—SSRIs.*)



Message is sent across synaptic gap.
Message is received; excess serotonin molecules are reabsorbed by sending neuron.
Prozac partially blocks normal reuptake of the neurotransmitter serotonin; excess serotonin in synapse enhances its mood-lifting effect.

Figure 73.1
Myers/DeWall, *Myers’ Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 73.1 Biology of antidepressants

Shown here is the action of Prozac, which partially blocks the reuptake of serotonin.

Some of the older antidepressant drugs work by blocking the reabsorption or breakdown of both norepinephrine and serotonin. Though effective, these dual-action drugs have more potential side effects, such as dry mouth, weight gain, hypertension, or dizzy spells (Anderson, 2000; Mulrow, 1999). Administering them by means of a patch, which bypasses the intestines and liver, helps reduce such side effects (Bodkin & Amsterdam, 2002). Some professionals prefer the SSRIs over other antidepressants (Jakubovski et al., 2015; Kramer, 2011).

Peter C. Vey/The New Yorker Collection.cartooonbank.com

"If this doesn't help you don't worry, it's a placebo."

But be advised: Patients with depression who begin taking these medications do not wake up the next day singing, "It's a beautiful day!" SSRIs begin to influence neurotransmission within hours, but their full psychological effect may take four weeks (and may involve a side effect of diminished sexual desire). One possible reason for the delay is that increased serotonin promotes new synapses plus *neurogenesis*—the birth of new brain cells—perhaps reversing stress-induced loss of neurons (Launay et al., 2011). Researchers are also exploring the possibility of quicker-acting antidepressants. One, ketamine, which is also an anesthetic and a party drug, blocks hyperactive receptors for glutamate, a neurotransmitter, and causes a burst of new synapses. It can provide relief from depression within hours of an infusion, often after transient hallucinations (Grimm & Scheidegger, 2013; McGirr et al., 2015; Naughton et al., 2014). But the relief often dissipates in a week (Kishimoto et al., 2016). Some drug companies are hoping to develop a ketamine-like, fast-acting drug without its side effects (Kirby, 2015).

Antidepressant drugs are not the only way to give the body a lift. Aerobic exercise can calm people who feel anxious, energize those who feel depressed, and offer other positive side effects (more on that topic later in this module). Cognitive therapy, by helping people reverse their habitual negative thinking style, can boost drug-aided relief from depression and reduce posttreatment relapses (Amick et al., 2015). Some clinicians attack depression (and anxiety) from both below and above

(Cuijpers et al., 2010; Hollon et al., 2014; Kennard et al., 2014): They use antidepressant drugs (which work, bottom-up, on the emotion-forming limbic system) in conjunction with cognitive-behavioral therapy (which works, top-down, to alter frontal lobe activity and change thought processes).

Researchers generally agree that people with depression often improve after a month on antidepressant drugs. But after allowing for natural recovery and the placebo effect, how big is the drug effect? Not big, report some researchers (Kirsch et al., 1998, 2014, 2016). In double-blind clinical trials, placebos produced improvement comparable to about 75 percent of the active drug's effect. For those with severe depression, the placebo effect is less and the added drug benefit somewhat greater (Fournier et al., 2010; Kirsch et al., 2008; Olfson & Marcus, 2009). Given that antidepressants often have unwanted side effects, and that aerobic exercise and cognitive behavioral therapy are also effective antidotes to mild or moderate depression, Irving Kirsch (2016) recommends more limited antidepressant use: "If they are to be used at all, it should be as a last resort."

Mood-Stabilizing Medications

In addition to antipsychotic, antianxiety, and antidepressant drugs, psychiatrists have *mood-stabilizing drugs* in their arsenal. One of them, Depakote, was originally used to treat epilepsy. It was also found effective in controlling the manic episodes associated with bipolar disorder. Another, the simple salt *lithium*, effectively levels the emotional highs and lows of this disorder.

The New Yorker Collection, 2000, P.C. Vey from cartoonbank.com.
All Rights Reserved.

“First of all I think you should know that last quarter’s sales figures are interfering with my mood-stabilizing drugs.”

Australian physician John Cade discovered the benefits of lithium in the 1940s when he administered it to a patient with severe mania and the patient became well in less than a week (Snyder, 1986). About 7 in 10 people with bipolar disorder benefit from a long-term daily dose of this cheap salt, which helps prevent or ease manic episodes and, to a lesser extent, lifts depression (Solomon et al., 1995). Kay Redfield Jamison (1995, pp. 88–89) described the effect:

> Lithium prevents my seductive but disastrous highs, diminishes my depressions, clears out the wool and webbing from my disordered thinking, slows me down, gentles me out, keeps me from ruining my career and relationships, keeps me out of a hospital, alive, and makes psychotherapy possible.

Taking lithium also correlates with a lower risk of suicide among people with bipolar disorder—to about one-sixth the risk of those not taking lithium (Oquendo et al., 2011). Naturally occurring lithium in drinking water has also correlated with lower suicide rates (across 18 Japanese cities and towns) and lower crime rates (across 27 Texas counties) (Ohgami et al., 2009; Schrauzer & Shrestha, 1990, 2010; Terao et al., 2010). Lithium works.

Brain Stimulation

73-3 How are brain stimulation and psychosurgery used in treating specific disorders?

Electroconvulsive Therapy

Another biomedical treatment, **electroconvulsive therapy (ECT)**, manipulates the brain by shocking it. When ECT was first introduced in 1938, the wide-awake patient was strapped to a table and jolted with electricity to the brain. The procedure, which produced convulsions and brief unconsciousness, gained a barbaric image. Although that image lingers, today’s ECT is much kinder and gentler, and no longer “convulsive.” The patient receives a general anesthetic and a muscle relaxant (to prevent bodily convulsions). A psychiatrist then delivers a brief pulse of electrical current, sometimes only to the brain’s right side, which triggers a 30- to 60-second seizure (McCall et al., 2017). Within 30 minutes, the patient awakens and remembers nothing of the treatment or of the preceding hours.

electroconvulsive therapy (ECT)

a biomedical therapy for severely depressed patients in which a brief electric current is sent through the brain of an anesthetized patient.

Study after study confirms that ECT can effectively treat severe depression in “treatment-resistant” patients who have not responded to drug therapy (Bailine et al., 2010; Fink, 2009; Lima et al., 2013; Medda et al., 2015). After three such sessions each week for two to four weeks, 70 percent or more of those receiving today’s ECT improve markedly, without discernible brain damage and with less memory loss than with earlier versions of ECT (HMHL, 2007). ECT also reduces suicidal thoughts and has been credited with saving many from suicide (Kellner et al., 2006). A *Journal of the American Medical Association* editorial concluded that “the results of ECT in treating severe depression are among the most positive treatment effects in all of medicine” (Glass, 2001).

FYI

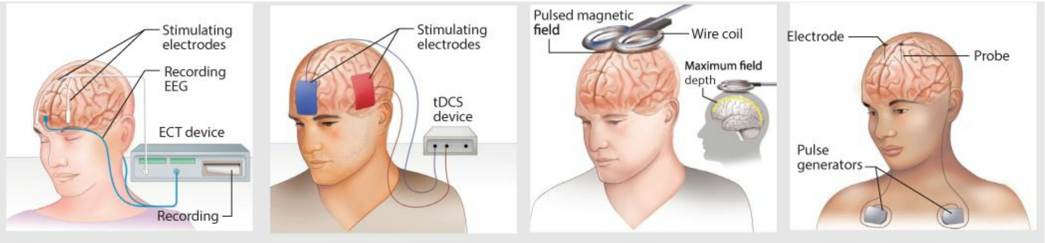
The medical use of electricity is an ancient practice. Physicians treated the Roman Emperor Claudius (10 B.C.E.–54 C.E.) for headaches by pressing electric eels to his temples.

How does ECT alleviate severe depression? After more than 70 years, no one knows for sure. One recipient likened ECT to the smallpox vaccine, which was saving lives before we knew how it worked. Perhaps the brief electric current calms neural centers where overactivity produces depression. Some research indicates that ECT stimulates neurogenesis (new neurons) and new synaptic connections within the hippocampus and amygdala (Joshi et al., 2016; Rotheneichner et al., 2014).

No matter how impressive the results, the idea of electrically shocking a person’s brain still strikes many as barbaric, especially given our ignorance about why ECT works. Moreover, the mood boost may not last long. Many ECT-treated patients eventually relapse back into depression, although relapses are somewhat fewer for those who also receive antidepressant drugs or who do aerobic exercise (Rosenquist et al., 2016; Salehi et al., 2016). *The bottom line:* In the minds of many psychiatrists and patients, ECT is a lesser evil than severe depression’s misery, anguish, and risk of suicide. As research psychologist Norman Endler (1982) reported after ECT alleviated his deep depression, “A miracle had happened in two weeks.”

Alternative Neurostimulation Therapies

Three other neural stimulation techniques—mild cranial electrical stimulation, magnetic stimulation, and deep-brain stimulation—also aim to treat the depressed brain (**Figure 73.2**).



Electroconvulsive therapy (ECT) Psychiatrist administers a strong current, which triggers a seizure in the anesthetized patient.

Transcranial direct current stimulation (tDCS) Psychiatrist applies a weak current to the scalp.

Repetitive transcranial magnetic stimulation (rTMS) Psychiatrist sends a painless magnetic field through the skull to the surface of the cortex to alter brain activity.

Deep-brain stimulation (DBS) Psychiatrist stimulates electrodes implanted in "sadness centers" to calm those areas.

Figure 73.2
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 73.2 A stimulating experience

Today's neurostimulation therapies apply strong or mild electricity, or magnetic energy, either to the skull's surface or directly to brain neurons.

TRANSCRANIAL ELECTRICAL STIMULATION

In contrast to ECT, which produces a brain seizure with about 800 milliamps of electricity, *transcranial direct current stimulation (tDCS)* administers a weak 1- to 2-milliamp current to the scalp. The current is so mild that some people have attempted to use tDCS machines to stimulate their own cognitive abilities, though skeptics argue that such a current is too weak to penetrate to the brain and that studies do not confirm cognitive benefits (Horvath et al., 2015; Underwood, 2016). After reviewing recent studies, two European expert panels did, however, report "probable efficacy" of tDCS as a depression treatment (Brunoni et al., 2016; Lefaucheur et al., 2017).

FYI

A meta-analysis of 17 clinical experiments found that one other stimulation procedure alleviates depression: massage therapy (Hou et al., 2010).

MAGNETIC STIMULATION

Depressed moods also sometimes improve when a painless procedure—called **repetitive transcranial magnetic stimulation (rTMS)**—is performed on wide-awake patients over several weeks. Repeated pulses surging through a magnetic coil held close to the skull can stimulate or suppress activity in areas of the cortex. Like tDCS (and unlike ECT), the rTMS procedure produces no memory loss or other serious side effects, aside from possible headaches.

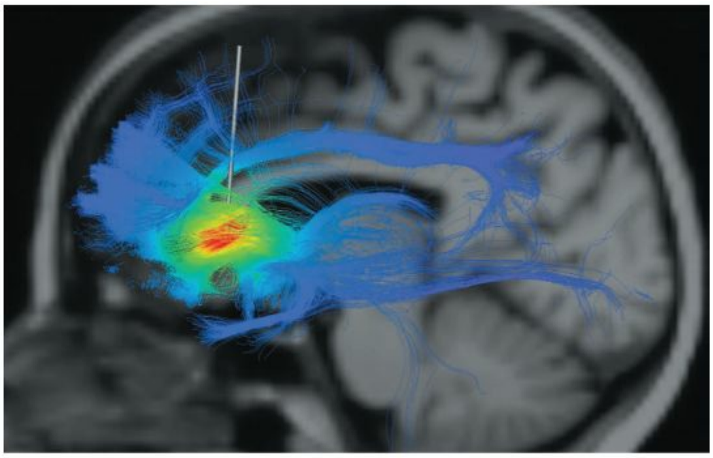
repetitive transcranial magnetic stimulation (rTMS)
the application of repeated pulses of magnetic energy to the brain; used to stimulate or suppress brain activity.

Some studies have found that, for 30 to 40 percent of people with depression, rTMS works (Becker et al., 2016; Brunoni et al., 2017; Taylor et al., 2017). How it works is unclear. One possible explanation is that the stimulation energizes the brain's left frontal lobe, which is relatively inactive during depression (Helmuth, 2001). Repeated stimulation may cause nerve cells to form new functioning circuits through the process of *long-term potentiation* (see Module 32 for more details on LTP). More research will shed light on how rTMS works, and for whom.

DEEP-BRAIN STIMULATION

Other patients whose depression has resisted both drugs and ECT have benefited from an experimental treatment pinpointing a neural hub that bridges the thinking frontal lobes to the limbic system (Becker et al., 2016; Brunoni et al., 2017; Ryder & Holtzheimer, 2016). This area, which is overactive in the brain of a depressed or temporarily sad person, calms when treated by ECT or antidepressants. To experimentally activate neurons that inhibit this negative activity, neuroscientist Helen Mayberg drew upon *deep-brain stimulation* (DBS) technology, sometimes used to treat Parkinson's tremors. Since 2003, she and her colleagues have used DBS to treat some 200 depressed patients via implanted electrodes in a brain area that functions as the neural "sadness center" (Lozano & Mayberg, 2015). About one-third reportedly have responded "extremely well" and another 30 percent have modestly improved (Underwood, 2013). Some felt suddenly more aware and became more talkative and engaged;

others improved only slightly, if at all. Other studies have found little benefit when DBS is compared to placebo electrode treatments (Witter & Ward, 2016). Future research will explore whether Mayberg has discovered a switch that can lift depression.



Helen Mayberg, M.D. Psychiatric Neuroimaging and Therapeutics, The Mayberg Lab at Emory University, Atlanta, GA/V. J. Wedeen and L. L.Wald/Athinoula A. Martinos Center For Biomedical Imaging and The Human Connectome Project, Boston, MA

A depression switch? By comparing the brains of patients with and without depression, researcher Helen Mayberg identified a brain area (highlighted in red) that appears active in people who are depressed or sad, and whose activity may be calmed by deep-brain stimulation.

Psychosurgery

Because its effects are irreversible, **psychosurgery**—surgery that removes or destroys brain tissue—is the most drastic and least-used biomedical intervention for changing behavior. In the 1930s, Portuguese physician Egas Moniz developed what would become the best-known psychosurgical operation: the **lobotomy**. Moniz found that cutting the nerves connecting the frontal lobes with the emotion-controlling centers of the inner brain calmed uncontrollably emotional and violent patients. In what would later become, in others' hands, a crude but quick and easy procedure, a neurosurgeon would shock the patient into a coma, hammer an icepick-like instrument through the top of each eye socket into the brain, and then wiggle it to sever connections running up to the frontal lobes. Between 1936 and 1954, tens of thousands of severely disturbed people were "lobotomized" (Valenstein, 1986).

psychosurgery

surgery that removes or destroys brain tissue in an effort to change behavior.

lobotomy

a psychosurgical procedure once used to calm uncontrollably emotional or violent patients. The procedure cut the nerves connecting the frontal lobes to the emotion-controlling centers of the inner brain.

New York Times Co./Getty Images

Failed lobotomy This 1940 photo shows Rosemary Kennedy (center) at age 22 with brother (and future U.S. president) John and sister Jean. A year later her father, on medical advice, approved a lobotomy that was promised to control her reportedly violent mood swings. The procedure left her confined to a hospital with an infantile mentality until her death in 2005 at age 86.

Although the intention was simply to disconnect emotion from thought, the effect was often more drastic. A lobotomy usually decreased the person’s misery or tension, but also produced a permanently lethargic, immature, uncreative person. During the 1950s, after some 35,000 people had been lobotomized in the United States alone, calming drugs became available and psychosurgery became scorned.

Today, lobotomies are history. More precise, microscale psychosurgery is sometimes used in extreme cases. For example, if a patient suffers uncontrollable seizures, surgeons can deactivate the specific nerve clusters that cause or transmit the convulsions. MRI-guided precision surgery is also occasionally done to cut the circuits involved in severe obsessive-compulsive disorder (Carey, 2009, 2011; Sachdev & Sachdev, 1997). Because these procedures are irreversible, neurosurgeons perform them only as a last resort.

* * *

Table 73.1 summarizes some aspects of the biomedical therapies we've discussed.

TABLE 73.1 Comparing Biomedical Therapies

Therapy	**Presumed Problem**	**Therapy Aim**	**Therapy Technique**
Therapeutic lifestyle change	Stress and unhealthy lifestyle	Restore healthy biological state.	Alter lifestyle through adequate exercise, sleep, nutrition, and other changes.
Drug therapies	Neurotransmitter malfunction	Control symptoms of psychological disorders.	Alter brain chemistry through drugs.
Brain stimulation	Depression (ECT is used only for severe, treatment-resistant depression.)	Alleviate depression, especially when it is unresponsive to drugs or other forms of therapy.	Stimulate brain through electroconvulsive shock, mild electrical stimulation, magnetic impulses, or deep-brain stimulation.
Psychosurgery	Brain malfunction	Relieve severe disorders.	Remove or destroy brain tissue.

Ask Yourself

- If a troubled friend asked, how would you summarize the available biomedical therapies?

Test Yourself

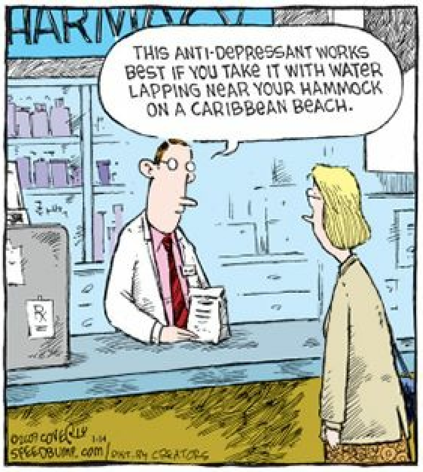
- How do researchers determine if particular drug therapies are effective?
- The drugs given most often to treat depression are called _______________. Schizophrenia is often treated with _______________ drugs.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Preventing Psychological Disorders and Building Resilience

73-4 What is the rationale for preventive mental health programs, and why is it important to develop resilience?

Psychotherapies and biomedical therapies tend to locate the cause of psychological disorders within the person. We infer that people who act cruelly must be cruel and that people who act “crazy” must be “sick.” We attach labels to such people, thereby distinguishing them from “normal” folks. It follows, then, that we try to treat “abnormal” people by giving them insight into their problems, by changing their thinking, by helping them gain control with drugs.



THIS ANTI-DEPRESSANT WORKS BEST IF YOU TAKE IT WITH WATER LAPPING NEAR YOUR HAMMOCK ON A CARIBBEAN BEACH.
SPEEDBUMP.com / DIST. BY CREATORS

Dave Coverly/Speed Bump

There is an alternative viewpoint: We could interpret many psychological disorders as understandable responses to a disturbing and stressful society. According to this view, it is not just the person who needs treatment, but also the person’s social context. Better to prevent a problem by reforming an unhealthy situation and by developing people’s coping competencies than to wait for and treat problems.

Preventive Mental Health

A story about the rescue of a drowning person from a rushing river illustrates this viewpoint: Having successfully administered first aid to the first victim, the rescuer spots another struggling person and pulls her out, too. After a half-dozen repetitions, the rescuer suddenly turns and starts running away while the river sweeps yet another floundering person into view. “Aren’t you going to rescue that fellow?” asks a bystander. “Heck no,” the rescuer replies. “I’m going upstream to find out what’s pushing all these people in.”

Preventive mental health is upstream work. It seeks to prevent psychological casualties by identifying and alleviating the conditions that cause them. As George Albee (1986, 2006) pointed out, there is abundant evidence that poverty, meaningless work, constant criticism, unemployment, racism, and sexism undermine people’s sense of competence, personal control, and self-esteem. Such stresses increase their risk of depression, alcohol use disorder, and suicide.

> “*It is better to prevent than to cure.*”
>
> *Peruvian folk wisdom*

To prevent psychological casualties we should, Albee contended, support programs that alleviate these demoralizing situations. We eliminated smallpox not by treating the afflicted but by inoculating the unafflicted. We conquered yellow fever by controlling mosquitoes. Better to drain the swamps than swat the mosquitoes.

Preventing psychological problems means empowering those who have learned an attitude of helplessness and changing environments that breed loneliness. It means renewing fragile family ties and boosting parents’ and teachers’ skills at nurturing children’s competence and belief in their abilities. It means harnessing positive psychology interventions to enhance human flourishing. In short, “everything aimed at improving the human condition, at making life more fulfilling and meaningful, may be considered part of primary prevention of mental or emotional disturbance” (Kessler & Albee, 1975, p. 557). Prevention can sometimes provide a double payoff. People with a strong sense of life’s meaning are more engaging socially (Stillman et al., 2011). If we can strengthen people's sense of meaning in life, we may also lessen their loneliness as they grow into more engaging companions.

Among the upstream prevention workers are *community psychologists.* Mindful of how people interact with their environment, they focus on creating environments that support psychological health. Through their research and social action, community psychologists aim to empower people and to enhance their competence, health, and well-being.

> “ *Mental disorders arise from physical ones, and likewise physical disorders arise from mental ones.* ”
>
> The Mahabharata, *200 B.C.E.*

Building Resilience

Preventive mental health includes efforts to build individuals' **resilience**—the ability to cope with stress and recover from adversity.

resilience

the personal strength that helps most people cope with stress and recover from adversity and even trauma.

Faced with unforeseen trauma, most adults exhibit resilience. This was true of New Yorkers in the aftermath of the September 11 terror attacks, especially those who enjoyed supportive close relationships and who had not recently experienced other stressful events (Bonanno et al., 2007). More than 9 in 10 New Yorkers, although stunned and grief-stricken by 9/11, did *not* have a dysfunctional stress reaction. Among those who did, the stress symptoms were mostly gone by the following January (Person et al., 2006). Even most combat-stressed veterans, most political rebels who have survived torture, and most people with spinal cord injuries do not later exhibit posttraumatic stress disorder (Bonanno et al., 2012; Mineka & Zinbarg, 1996).

Struggling with challenging crises can even lead to **posttraumatic growth**. Many cancer survivors have reported a greater appreciation for life, more meaningful relationships, increased personal strength, changed priorities, and a richer spiritual life (Tedeschi & Calhoun, 2004). Americans who tried to make sense of the 9/11 terror attacks experienced less distress (Park et al., 2012). Out of even our worst experiences, some good can come, especially when we can imagine new possibilities (Roepke, 2015; Roepke & Seligman, 2015). Suffering can beget new sensitivity and strength.

posttraumatic growth
positive psychological changes as a result of struggling with extremely challenging circumstances and life crises.

✓ Check Your Understanding

Ask Yourself

- Can you think of a specific way that improving the environment in your own community might prevent some psychological disorders among its residents?

Test Yourself

- Severe depression that has not responded to other therapy may be treated with _______________ _______________, which can cause brain seizures and memory loss. More moderate neural stimulation techniques designed to help alleviate depression include _______________ direct current stimulation, _______________ _______________ magnetic stimulation, and _______________-_______________ stimulation.
- What is the difference between preventive mental health and the psychological and biomedical therapies?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 73 REVIEW

73-1 Why is therapeutic lifestyle change considered an effective biomedical therapy, and how does it work?

- Therapeutic lifestyle change is considered a biomedical therapy because it influences the way the brain responds. Mind and body are a unit; affect one and you will affect the other. Our exercise, nutrition, relationships, recreation, relaxation, and religious or spiritual engagement affect our mental health.
- People who undergo a program of aerobic exercise, adequate sleep, light exposure, social engagement, rumination reduction, and better nutrition have gained relief from depressive symptoms.

73-2 What are the drug therapies? How do double-blind studies help researchers evaluate a drug's effectiveness?

- *Psychopharmacology,* the study of drug effects on mind and behavior, has helped make drug therapy the most widely used biomedical therapy.
- *Antipsychotic drugs,* used in treating schizophrenia, block dopamine activity. Side effects may include tardive dyskinesia (with involuntary movements of facial muscles, tongue, and limbs) or increased risk of obesity and diabetes.
- *Antianxiety drugs,* which depress central nervous system activity, are used to treat anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder. These drugs can be physically and psychologically addictive.
- *Antidepressant drugs,* which increase the availability of serotonin and norepinephrine, are used for depression, often with modest effectiveness beyond that of placebo drugs. The antidepressants known as selective serotonin reuptake inhibitors (SSRIs) are now used to treat other disorders, including strokes, anxiety disorders, obsessive-compulsive

disorder, and posttraumatic stress disorder.

- Lithium and Depakote are mood stabilizers prescribed for those with bipolar disorder.
- Studies may use a double-blind procedure to avoid the placebo effect and researchers’ bias.

73-3 How are brain stimulation and psychosurgery used in treating specific disorders?

- *Electroconvulsive therapy (ECT)*, in which a brief electric current is sent through the brain of an anesthetized patient, is an effective treatment for people with severe depression who have not responded to other therapy.
- *Transcranial direct current stimulation (tDCS)* administers a far weaker current to the scalp.
- Newer alternative treatments for depression include *repetitive transcranial magnetic stimulation (rTMS)* and, in preliminary clinical experiments, deep-brain stimulation that calms an overactive brain region linked with negative emotions.
- *Psychosurgery* removes or destroys brain tissue in hopes of modifying behavior.
  - Radical psychosurgical procedures such as the *lobotomy* were once popular, but neurosurgeons now rarely perform brain surgery to change behavior or moods.
  - Brain surgery is a last-resort treatment because its effects are irreversible.

73-4 What is the rationale for preventive mental health programs, and why is it important to develop resilience?

- Preventive mental health programs are based on the idea that many psychological disorders could be prevented by changing oppressive, esteem-destroying environments into more benevolent, nurturing environments that foster growth, self-confidence, and *resilience*.

- Building resilience might prevent some disorders or even enable *posttraumatic growth*.

Multiple-Choice Questions

1. Which neurotransmitter is affected by antipsychotic medications?

  a. Epinephrine
  b. Dopamine
  c. Norepinephrine
  d. Acetylcholine
  e. Serotonin

2. Which of the following is most effectively treated with electroconvulsive therapy (ECT)?

  a. Psychosis
  b. Schizophrenia
  c. Obsessive-compulsive disorder
  d. Depression
  e. Generalized anxiety disorder

3. Having been diagnosed with bipolar disorder, Patricia has been prescribed **_____** to level the highs and lows of the disorder.

  a. Xanax
  b. Lithium
  c. Zoloft
  d. Paxil
  e. Ativan

4. Juliette's depression is not responding to the normal biomedical treatments. Her therapist has suggested that she try several sessions of _____ to energize her left frontal lobe and reduce her symptoms.

  a. psychosurgery
  b. rTMS
  c. ECT
  d. CBT

e. REBT

Practice FRQs

1. Francisco has been diagnosed with major depressive disorder. Explain how each of the following might alleviate his symptoms.
   - SSRIs
   - Deep-brain stimulation

Answer

1 point: SSRIs would help alleviate Francisco’s symptoms by making more serotonin available to neurons. By increasing the levels of serotonin, his symptoms should be reduced. Page 754

1 point: Deep-brain stimulation uses implanted electrodes to target an area of the brain where the frontal lobes connect to the limbic system—an area that tends to be overactive in people with depression. Inhibiting negative activity in this way for Francisco should help relieve his symptoms. Page 757

2. Briefly describe four therapeutic lifestyle changes and their mental health benefits.

AP® Exam Practice Questions

Multiple-Choice Questions

1. In an effort to help a child overcome a fear of cats, a therapist pairs a trigger stimulus (something associated with cats) with a new stimulus (for example, an appealing snack or toy) that causes an emotional response that is incompatible with fear. Which clinical orientation is this therapist using?

a. Psychodynamic
b. Behavioral

c. Biomedical
d. Client-centered
e. Humanistic

2. Which of the following is a similarity between humanistic and psychoanalytic therapies?

a. Both approaches focus on the present more than the past.
b. Both approaches are more concerned with conscious than with unconscious feelings.
c. Both approaches focus on taking immediate responsibility for one’s feelings.
d. Both approaches focus on personal growth instead of curing illness.
e. Both approaches are generally considered insight therapies.

3. Lea, a client with depression, has been visiting a therapist for several months. During each session, she is challenged on her irrational thinking. The therapist is likely using Albert Ellis’ version of

a. rational-emotive behavioral therapy.
b. aversive conditioning.
c. insight therapy.
d. client-centered therapy.
e. rTMS.

4. Some patients whose depression resists drugs have benefited from which experimental treatment?

a. Transference
b. Meta-analysis
c. Antipsychotic drugs
d. Deep-brain stimulation
e. Resistance

5. Carlos has been prescribed an SSRI to treat his illness. This type of drug is classified as a(n)

a. antidepressant.
b. antipsychotic.

c. antianxiety.
d. mood-stabilizer.
e. bipolar disorder drug.

6. Which of the following is seen as an effective treatment for severe depression that does not respond to drug therapy?

a. Lobotomy
b. Token economy
c. ECT
d. Classical conditioning
e. EMDR therapy

7. Echoing, restating, and seeking clarification of what a person expresses (verbally or nonverbally) in a therapy session is called

a. active listening.
b. virtual reality exposure therapy.
c. systematic desensitization.
d. family therapy.
e. classical conditioning.

8. Challenging people’s automatic negative thoughts is a key characteristic of the therapy developed by

a. Sigmund Freud.
b. B. F. Skinner.
c. Aaron Beck.
d. Gordon Allport.
e. Carl Rogers.

9. In which kind of therapy would the therapist be most likely to note the following during a session: “Blocks in the flow of free associations indicate resistance”?

a. Cognitive therapy
b. Psychoanalysis
c. Client-centered therapy
d. Behavioral therapy

e. Person-centered therapy

0. Therapists who encourage their clients to change their thoughts and their actions are engaging in

a. aversive conditioning.
b. psychodynamic therapy.
c. client-centered therapy.
d. family therapy.
e. cognitive-behavioral therapy.

1. Allowing people to discover, in a social context, that others have problems similar to their own is a unique benefit of

a. psychodynamic therapy.
b. psychopharmacological therapy.
c. humanistic therapy.
d. cognitive therapy.
e. group therapy.

2. Which of the following therapeutic approaches is scientifically supported?

a. Recovered-memory therapies
b. Rebirthing therapies
c. Cognitive therapy
d. Energy therapies
e. Facilitated communication therapy

3. Most antipsychotic drugs mimic a certain neurotransmitter by blocking its activity at the receptor sites. These drugs affect the neurotransmitter

a. adrenaline.
b. epinephrine.
c. serotonin.
d. dopamine.
e. acetylcholine.

4. Which of the following is *not* recommended by therapists as a way to help prevent or get over depression?

a. Recovered-memory therapies
b. Aerobic exercise
c. Light exposure
d. Increased social connections
e. Anti-rumination strategies

5. A psychotherapist states, “Getting people to change what they say to themselves is an effective way to change their thinking.” This statement best exemplifies which kind of therapeutic approach?

a. Behavioral
b. Psychodynamic
c. Biomedical
d. Cognitive
e. Active listening

6. Treatment for obsessive-compulsive disorder could include

a. antianxiety drugs.
b. antidepressant drugs.
c. lithium.
d. a & b only
e. b & c only

7. Colten visits a therapist for his depression. In addition to talking to Colten about his problems, the therapist also prescribes medication. This therapist is most likely to be a

a. psychiatrist.
b. clinical psychologist.
c. social worker.
d. clinical social worker.
e. counselor.

8. After overcoming severe anxiety and dealing with some physical health issues, Grace finds herself having a greater appreciation for life and a sense of increased personal strength. Her psychotherapist identifies this as

a. transference.
b. resistance.
c. posttraumatic growth.
d. humanism.
e. behavior modification.

9. When used in conjunction with antidepressant drugs, ______ is especially effective in the treatment of depression.

a. psychosurgery
b. behavior modification therapy
c. cognitive-behavioral therapy
d. client-centered therapy
e. insight therapy

0. Therapists who help people understand their current symptoms by focusing on important relationships, including childhood experiences and the therapist-client relationship, are most likely to be considered

a. biomedical therapists.
b. psychoanalytic therapists.
c. humanistic therapists.
d. psychodynamic therapists.
e. exposure therapists.

Free-Response Questions

1. Your friend Lawrence recently confided in you that he has been diagnosed with major depressive disorder. He has been offered several different kinds of treatment: psychodynamic therapy, exposure therapy, REBT, SSRIs, and rTMS. Explain what you would tell Lawrence about how each type of therapy works and whether research indicates that it might be an effective treatment for major depressive disorder.

Rubric for Free Response Question 1

1 point: Psychodynamic therapy involves a therapist and client working together to gain insight about a client’s unconscious conflicts and childhood experiences. Outcome research indicates that psychodynamic therapy has had success in alleviating depression symptoms. Page 724

1 point: To extinguish fear or anxiety, exposure therapy repeatedly brings people into contact with fear-or anxiety-arousing stimuli. This type of therapy is specifically focused on reducing anxiety and fear and is not designed to treat depression. Page 730

1 point: Albert Ellis’ rational-emotive behavior therapy (REBT), a type of cognitive therapy, attempts to stop irrational thinking by challenging a person’s illogical, self-defeating assumptions. Since many of the symptoms of depression involve negative, pessimistic thinking, REBT is worth exploring as a treatment for depression. Page 733

1 point: SSRIs, such as Zoloft, Paxil, and Prozac, work by partially blocking the reabsorption and removal of serotonin from synapses. Having more serotonin remain in the synapses has been shown to help reduce the symptoms of depression. Page 754

1 point: Repetitive transcranial magnetic stimulation (rTMS) sends repeated pulses of magnetic energy into the brain, usually into the left frontal lobe. This approach has shown effectiveness in the treatment of depression. Page 757

2. For each of the following pairs, first define the treatment referenced. Then explain the rationale for using that treatment for an individual with the disorder indicated.

- Bipolar disorder and drug therapy
- Phobias and systematic desensitization
- Dissociative identity disorder and psychoanalysis
- Addiction and group therapy
- Depression and rational-emotive behavior therapy (REBT)

(5 points)

2. Max wants to stop smoking but is unable to do so on his own. How would a therapist from each of the following approaches attempt to help him stop smoking?

- Psychoanalytic
- Cognitive
- Behavioral

(3 points)

MODULES

74 Attribution, Attitudes, and Actions

75 Conformity and Obedience

76 Group Behavior

77 Prejudice and Discrimination

78 Aggression

79 Attraction

80 Altruism, Conflict, and Peacemaking

Dirk Willems faced a moment of decision in 1569. Threatened with torture and death as a member of a persecuted religious minority, he escaped from his Asperen, Holland, prison and fled across an ice-covered pond. His stronger and heavier jailer pursued him but fell through the ice and, unable to climb out, pleaded for help.

With his freedom in front of him, Willems acted with ultimate selflessness. He turned back and rescued his pursuer, who, under orders, took him back to captivity. A few weeks later Willems was condemned to be "executed with fire, until death ensues." For his martyrdom, present-day Asperen has named a street in honor of its folk hero *(Toews, 2004)*.

What drives people to feel contempt for minority-group members, such as Dirk Willems, and to act so spitefully? What motivates people, such as his jailer, to carry out unfair orders? And what inspired the selflessness of Willems' response, and of so many who have died trying to save others? Indeed, what motivates any of us who volunteer kindness and generosity toward others?

As such examples demonstrate, we are social animals. We cannot live for ourselves alone, for we are connected with others by "a thousand fibres" through which "run [our] actions as causes, and return to [us] as effects" (Melvill, 1855). *Social psychologists* explore these connections by scientifically studying how we *think about*, *influence*, and *relate to* one another.

Unit XIV Overview Video

Module **74 Attribution, Attitudes, and Actions**

LEARNING TARGETS

- 74-1 Identify what social psychologists study, and discuss how we tend to explain others' behavior and our own.
- 74-2 Discuss how our attitudes and actions interact.

74-1 What do social psychologists study? How do we tend to explain others' behavior and our own?

Personality psychologists (Unit X) focus on the person. They study the personal traits and dynamics that explain why, in a given situation, *different people* act differently. (Would you have acted as Willems did, helping the jailer out of the icy water?) **Social psychologists** focus on the situation. They study the social influences that explain why *the same person* acts differently in *different situations*. (Might the jailer have acted differently—opting not to march Willems back to jail—under differing circumstances?)

social psychology

the scientific study of how we think about, influence, and relate to one another.

The Fundamental Attribution Error

Our social behavior arises from our social thinking (“social cognition”). Especially when the unexpected occurs, we want to understand and explain why people act as they do. After studying how people explain others’ behavior, Fritz Heider (1958) proposed an **attribution theory**: We can credit (attribute) the behavior to the person’s stable, enduring traits (a *dispositional attribution*), or we can attribute it to the situation (a *situational attribution*).

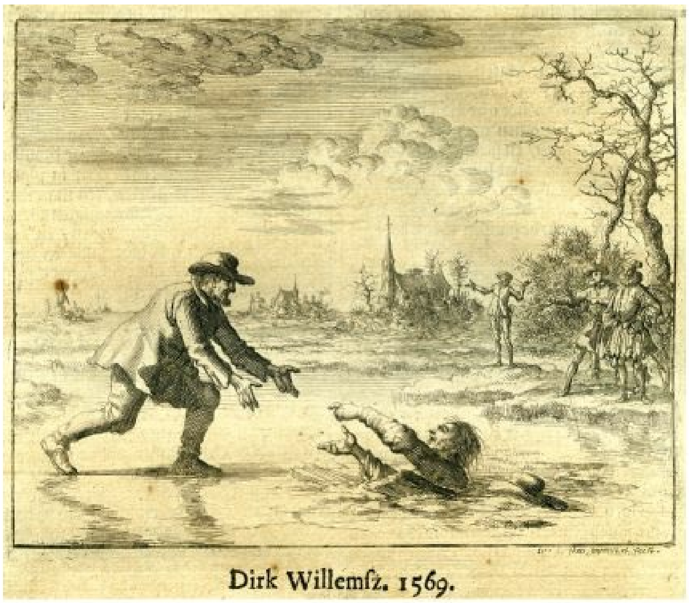
attribution theory

the theory that we explain someone’s behavior by crediting either the situation or the person’s disposition.

For example, in class, we notice that Juliette seldom talks. At the cafeteria, Jack talks nonstop. That must be the sort of people they are, we decide. Juliette must be shy and Jack outgoing. Such attributions—to their dispositions—can be valid. People do have enduring personality traits. But sometimes we fall prey to the **fundamental attribution error** (Ross, 1977): We overestimate the influence of personality and underestimate the influence of situations. In class, Jack may be as quiet as Juliette. Catch Juliette as the lead in the high school musical and you may hardly recognize your quiet classmate.

fundamental attribution error

the tendency for observers, when analyzing others’ behavior, to underestimate the impact of the situation and to overestimate the impact of personal disposition.



Dirk Willemſz. 1569.

Mennonite Library and Archives/Bethel College

An etching of Dirk Willems by Dutch artist Jan Luyken (from *The Martyrs Mirror,* 1685)

The fundamental attribution error was demonstrated in an experiment with Williams College students (Napolitan & Goethals, 1979). They had students talk, one at a time, with a woman who acted either cold and critical or warm and friendly. Before the conversations, the researchers told half the students that the woman's behavior would be spontaneous. They told the other half the truth—that they had instructed her to *act* friendly (or unfriendly).

Did hearing the truth affect students' impressions of the woman? Not at all! If the woman acted friendly, both groups decided she really was a warm person. If she acted unfriendly, both decided she really was a cold person. They attributed her behavior to her personal disposition *even when told that her behavior was situational*—that she was merely acting that way for the purposes of the experiment.

We all commit the fundamental attribution error. Consider: Is your AP® psychology teacher shy or outgoing?

If you answer "outgoing," remember that you know your teacher from only one situation—the classroom, where teaching demands talking. Your teacher might disagree: "Me, outgoing? It all depends on the situation. In class or with good friends, yes, I'm outgoing. But at professional meetings I'm really rather shy." Outside their assigned roles, teachers seem less teacherly, presidents less presidential, managers less managerial.

FYI

Unlike sociology, which studies societies and social groupings, social psychologists focus more on how *individuals* view and affect one another.

What Factors Affect Our Attributions?

One factor is culture. Individualist Westerners more often attribute behavior to people’s personal traits. People in East Asian cultures are somewhat more sensitive to the power of the situation (Kitayama et al., 2009; Riemer et al., 2014). In experiments that asked people to view scenes, such as a big fish swimming, Americans focused on the attributes of the individual fish. Japanese viewers focused more on the whole scene—the situation (Chua et al., 2005; Nisbett, 2003).

AP® EXAM TIP

Many students have not heard of the fundamental attribution error before taking a course in psychology. Be sure you can define the concept (which may appear on the AP® exam). Try illustrating this concept using your own attributions and those of others as examples.

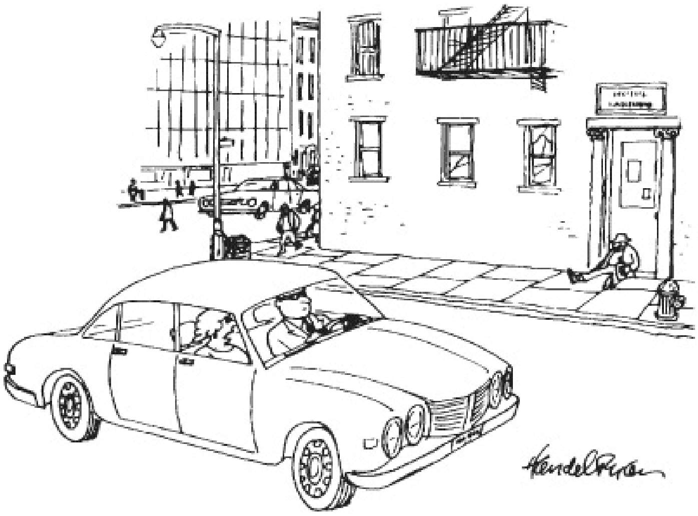
When we explain *our own* behavior, we are sensitive to how behavior changes with the situation (Idson & Mischel, 2001). After behaving badly, for example, we recognize how the situation affected our actions (recall the *self-serving bias* discussed in Module 59). We also are sensitive to the power of the situation when we explain the behavior of people we have seen in many different contexts. We more often commit the fundamental attribution error when a stranger acts badly. Having only seen that enraged fan screaming at the referee in the heat of competition, we may assume he is a bad person. But outside the stadium, he may be a good neighbor and a great parent.

As we act, our eyes look outward; we see others' faces, not our own. Would taking an observer's viewpoint make us more aware of our own personal style? Researchers tested this idea by using separate cameras to film two people interacting. When they showed each person a replay of the interaction—filmed from the other person's perspective—participants credited their own behavior more to their disposition, much as an observer typically would (Lassiter & Irvine, 1986; Storms, 1973).

There are two important exceptions to our usual view of our own actions: Our deliberate and *admirable* actions we often attribute to our own good reasons, not to the situation (Malle, 2006; Malle et al., 2007). And as we age, we tend to attribute our younger selves' behavior mostly to our traits (Pronin & Ross, 2006).

How Do Our Attributions Matter?

The way we explain others' actions (attributing them to the person or the situation) can have important real-life effects (Fincham & Bradbury, 1993; Fletcher et al., 1990). Does a warm greeting reflect romantic interest or social courtesy? Does a manager's criticism reflect a job threat or a bad day? Was a shooting malicious or an act of self-defense? Attributions matter.



J. B. Handelsman The New Yorker Collection/The Cartoon Bank

"Otis, shout at that man to pull himself together."

Do you attribute poverty and unemployment to social circumstances or to personal traits? In Britain, India, Australia, and the United States, political conservatives have tended to attribute responsibility to the personal dispositions of the poor and unemployed (Furnham, 1982; Pandey et al., 1982; Wagstaff, 1982; Zucker & Weiner, 1993). “People generally get what they deserve. Those who take initiative can still get ahead.” In experiments, those who reflect on the power of choice—either by recalling their own choices or taking note of another’s choices—become more likely to think that people get what they deserve (Savani & Rattan, 2012). Political liberals, and those not primed to consider the power of choice, are more likely to blame past and present situations: “If you or I had to live with the same poor education, lack of opportunity, and discrimination, would we be any better off?”

Lee Snider/The Image Works

An attribution question Whether we attribute poverty and homelessness to social circumstances or to personal dispositions affects and reflects our political views.

Richard Ellis/Alamy

Dispositional versus situational attributions Should the 2015 slaughter of nine African-Americans attending a church Bible study in Charleston, West Virginia, be attributed to the shooter’s disposition? (“There is one person to blame here. A person filled with hate,” said South Carolina governor Nikki Haley.) Or to America’s gun culture? (“At some point, we as a country will have to reckon with the fact that this type of mass violence does not happen in other advanced countries . . . with this kind of frequency,” said President Obama.) Or to both?

FYI

Some 7 in 10 college women report having experienced a man misattributing her friendliness as a sexual come-on (Jacques-Tiura et al., 2007).

The point to remember: Our attributions—to a person’s disposition or to the situation—have real consequences.

Attitudes and Actions

74-2 How do attitudes and actions interact?

Attitudes are feelings, often influenced by our beliefs, that predispose our reactions to objects, people, and events. If we *believe* someone is threatening us, we may *feel* fear and anger toward the person and *act* defensively. The traffic between our attitudes and our actions is two-way. Our attitudes affect our actions. And our actions affect our attitudes (much as our emotional expressions can affect our emotions).

attitude

feelings, often influenced by our beliefs, that predispose us to respond in a particular way to objects, people, and events.

Attitudes Affect Actions

In any debate, people on both sides attempt to convert the opposition and sway the undecided. Persuaders try to influence our behavior by changing our attitudes. But situational factors, such as strong social pressures, can override the attitude-behavior connection (Wallace et al., 2005). In roll-call votes, politicians may vote as their supporters demand, despite privately disagreeing (Nagourney, 2002).

Attitudes are especially likely to affect behavior when external influences are minimal, and when the attitude is stable, specific to the behavior, and easily recalled (Glasman & Albarracín, 2006). One experiment used vivid, easily recalled information to persuade White suntanning college students that repetitive tanning put them at risk for future skin cancer. One month later, 72 percent of the participants, and only 16 percent of those in a waitlist control group, had lighter skin (McClendon & Prentice-Dunn, 2001). Persuasion changed attitudes (about skin cancer risk), which changed behavior (less tanning).

Efforts to *persuade* generally take two forms:

- **Peripheral route persuasion** uses attention-getting cues to trigger emotion-based snap judgments. Endorsements by beautiful or famous people can influence people’s attitudes, whether the judgment is about choosing a political candidate or buying the latest smart phone. When green activist film star Leonardo DiCaprio urges action to counter climate change, or when Pope Francis (2015) states that “Climate change is a global problem with grave implications,” they hope to harness their credibility for peripheral route persuasion. Even if it doesn’t engage systematic thinking, it may produce fast results. The same is true of heart-tugging ads for greeting cards, pet adoption, or support for the starving.
- **Central route persuasion** offers evidence and arguments that trigger careful thinking. To persuade buyers to purchase a particular phone, an ad might itemize the phone’s great features. To marshal support for climate change intervention, effective arguments have focused on accumulating greenhouse gases, melting Arctic ice, rising world temperatures and seas, and extreme weather (van der Linden et al., 2015). Central route persuasion works well for people who are naturally analytical or involved in an issue. And because it is more thoughtful and less superficial, it is more durable.

peripheral route persuasion

occurs when people are influenced by incidental cues, such as a speaker’s attractiveness.

central route persuasion

occurs when interested people focus on the arguments and respond with favorable thoughts.

AP® EXAM TIP

Be sure you can identify examples of peripheral route persuasion and central route persuasion, and that you understand the difference.

Actions Affect Attitudes

Now consider a more surprising principle: Not only will we stand up for what we believe, we also will more strongly believe in what we have stood up for. Many streams of evidence confirm that *attitudes follow behavior* (**Figure 74.1**).

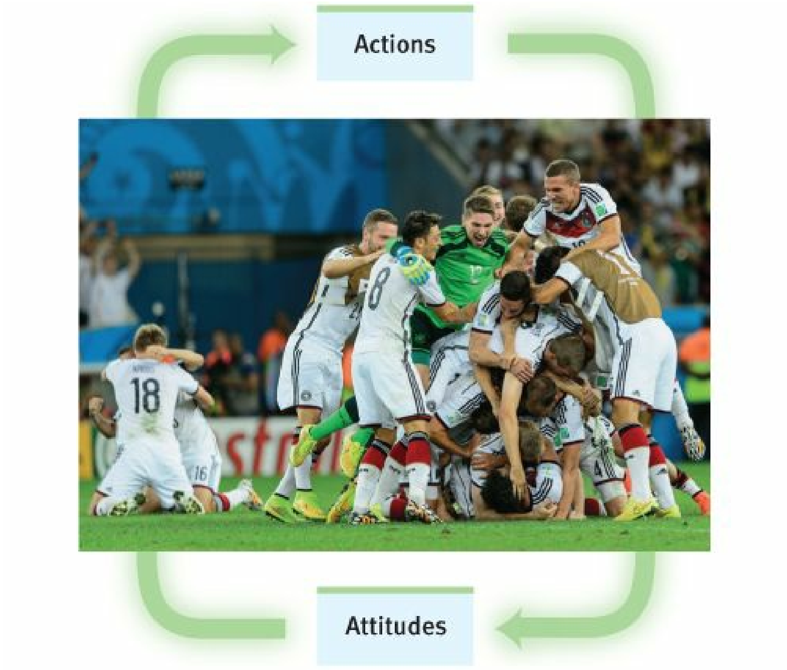


Figure 74.1
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e,
© 2018 Worth Publishers
Matthias Hangst/Getty Images

Figure 74.1 Attitudes follow behavior

Cooperative actions, such as those performed by people on sports teams (including Germany, shown here celebrating a World Cup victory), feed mutual liking. Such attitudes, in turn, promote positive behavior.

The Foot-in-the-Door Phenomenon

How would you react if someone induced you to act against your beliefs? In many cases, people adjust their attitudes. During the Korean war, many

U.S. prisoners were held in Chinese communist war camps. Without using brutality, the captors secured prisoners' collaboration in various activities, ranging from simple tasks (running errands to gain privileges) to more serious actions (false confessions, informing on other prisoners, and divulging military information). When the war ended, 21 prisoners chose to stay with the communists. More returned home "brainwashed"—convinced that communism was a good thing for Asia.

How did the Chinese captors achieve these amazing results? A key ingredient was their use of the **foot-in-the-door phenomenon**: They knew that people who agree to a small request will find it easier to comply later with a larger one. The Chinese began with harmless requests, such as copying a trivial statement, but gradually escalated their demands (Schein, 1956). The next statement to be copied might list flaws of capitalism. Then, to gain privileges, the prisoners participated in group discussions, wrote self-criticisms, or uttered public confessions. After doing so, they often adjusted their beliefs to be more consistent with their public acts. The point is simple: To get people to agree to something big, start small and build (Cialdini, 1993). A trivial act makes the next act easier. Succumb to a temptation and you will find the next temptation harder to resist.

foot-in-the-door phenomenon

the tendency for people who have first agreed to a small request to comply later with a larger request.

In dozens of experiments, researchers have coaxed people into acting against their attitudes or violating their moral standards, with the same result: Doing becomes believing. After giving in to a request to harm an innocent victim—by making nasty comments or delivering presumed electric shocks—people begin to disparage their victim. After speaking or writing on behalf of a position they have qualms about, they begin to believe their own words.

Fortunately, the attitudes-follow-behavior principle works with good deeds as well. In one classic experiment, researchers sought permission to place a large "Drive Carefully" sign in people's front yards (Freedman & Fraser, 1966). The 17 percent rate of agreement soared to 76 percent among those who first did a small favor—placing a 3-inch-high "Be a Safe Driver" sign in their window.

> *"If the King destroys a man, that's proof to the King it must have been a bad man."*
>
> *Thomas Cromwell, in Robert Bolt's* A Man for All Seasons, *1960*

The foot-in-the-door tactic has helped boost charitable contributions, blood donations, and U.S. school desegregation. With the passage of the Civil Rights Act of 1964, school desegregation became law. In the years that followed, White Americans expressed diminishing racial prejudice. And as Americans in different regions came to act more alike—thanks to more uniform national standards against discrimination—they began to think more alike.

Role-Playing Affects Attitudes

When you adopt a new **role**—when you become a college student or begin a new job—you strive to follow the social prescriptions. At first, your behaviors may feel phony, because you are acting a role. Soldiers may at first feel they are playing war games. Before long, however, what began as play acting in the theater of life becomes *you*.

role

a set of expectations (norms) about a social position, defining how those in the position ought to behave.

Role playing morphed into real life in one famous and controversial study in which male college students volunteered to spend time in a simulated prison. Stanford psychologist Philip Zimbardo (1972) randomly assigned some volunteers to be guards. He gave them uniforms, clubs, and whistles and instructed them to enforce certain rules. Others became prisoners, locked in barren cells and forced to wear humiliating outfits. For a day or two, the volunteers self-consciously “played” their roles. Then the simulation became real—too real. Some guards developed disparaging attitudes and a third “became tyrannical,” devising cruel and degrading routines. One by one, the prisoners broke down, rebelled, or became passively resigned. After only six days, Zimbardo called off the study.

> “*Fake it until you make it.*”
>
> *Alcoholics Anonymous saying*

Critics question the reliability of Zimbardo’s results (Griggs, 2014). But this much seems true: Role playing can train people to become torturers in the real world (Staub, 1989). In the early 1970s, the Greek military government eased men into their roles. First, a trainee stood guard outside an interrogation cell. After this “foot in the door” step, he stood guard inside. Only then was he ready to become actively involved in the questioning and torture. In one study of German men, military training toughened their personalities, leaving them less agreeable even five years later, after leaving the military (Jackson et al., 2012). What we do, we gradually become: Every time we act like the people around us, we slightly change ourselves to be more like them, and less like who we used to be.

Yet people differ. In Zimbardo’s simulation and in real-life atrocity-producing situations, some people have succumbed to the situation and others have not (Haslam & Reicher, 2007, 2012; Mastroianni & Reed, 2006; Zimbardo, 2007). Person and situation interact.

Cognitive Dissonance: Relief From Tension

▶ Flip It Video: Cognitive Dissonance Theory

So far, we have seen that actions can affect attitudes, sometimes turning prisoners into collaborators, doubters into believers, and compliant guards into abusers. But why? One explanation is that when we become aware that our attitudes and actions don't coincide, we experience mental tension, or *cognitive dissonance*. Indeed, the brain regions that become active when people experience other forms of mental tension and negative arousal also become active when people experience cognitive dissonance (Harmon-Jones et al., 2015; Kitayama et al., 2013). To relieve this tension, according to Leon Festinger's (1957) **cognitive dissonance theory**, we often bring our attitudes into line with our actions.

cognitive dissonance theory

the theory that we act to reduce the discomfort (dissonance) we feel when two of our thoughts (cognitions) are inconsistent. For example, when we become aware that our attitudes and our actions clash, we can reduce the resulting dissonance by changing our attitudes.

Left: Philip G. Zimbardo; Right: AP Photo

The power of the situation In his 1972 Stanford Prison simulation, Philip Zimbardo created a toxic situation (left). Those assigned to the guard role soon degraded the prisoners. In real life in 2004, some U.S. military guards tormented Iraqi prisoners at the U.S.-run Abu Ghraib prison (right). To Zimbardo (2004, 2007), it was a bad barrel rather than a few bad apples that led to the Abu Ghraib atrocities: "When ordinary people are put in a novel, evil place, such as most prisons, Situations Win, People Lose."

Dozens of experiments have tested the cognitive dissonance theory. Many have made people feel responsible for behavior that clashed with their attitudes and had foreseeable consequences. As a participant in one of these experiments, you might agree for a measly $2 to help a researcher by writing an essay supporting something you don’t believe in (perhaps school uniforms). Feeling responsible for the statements (which are inconsistent with your attitudes), you would probably feel dissonance, especially if you thought your essay might influence an administrator. To reduce the uncomfortable tension, you might start believing your phony words. It’s as if we rationalize, “If I chose to do it (or say it), I must believe in it.” The less coerced and more responsible we feel for a troubling act, the more dissonance we feel. The more dissonance we feel, the more motivated we are to find and project consistency, such as changing our attitudes to help justify the act.

The attitudes-follow-behavior principle has a heartening implication: We cannot directly control all our feelings, but we can influence them by altering our behavior. (Recall from Module 42 the emotional effects of facial expressions and body postures.) If we are depressed, we can alter our attributions and explain events in more positive terms, with more self-acceptance and fewer self-put-downs (Rubenstein et al, 2016). If we are unloving, we can become more loving by behaving *as if* we were loving—by doing thoughtful things, expressing affection, giving affirmation. “Each time you ask yourself, ‘How should I act?’” observes Robert Levine (2016), “you are also asking, ‘Who is the person I want to become?’” That helps explain why teens’ doing volunteer work promotes a compassionate identity. Pretense can become reality. Conduct sculpts character. What we do we become.

> “*Sit all day in a moping posture, sigh, and reply to everything with a dismal voice, and your melancholy lingers. . . . If we wish to conquer undesirable emotional tendencies in ourselves, we must . . . go through the outward movements of those contrary dispositions which we prefer to cultivate.*”
>
> *William James*, Principles of Psychology, *1890*

The point to remember: We can act ourselves into a way of thinking about as easily as we can think ourselves into a way of acting.

✓ Check Your Understanding

Ask Yourself

- Do you have an attitude or tendency you would like to change? Using the attitudes-follow-behavior principle, how might you go about changing that attitude?

Test Yourself

- Driving to school one snowy day, Marco narrowly misses a car that slides through a red light. “Slow down! What a terrible driver,” he thinks to himself. Moments later, Marco himself slips through an intersection and yelps, “Wow! These roads are awful. The city plows need to get out here.” What social psychology principle has Marco just demonstrated? Explain.
- How do our attitudes and our actions affect each other?
- When people act in a way that is not in keeping with their attitudes, and then change their attitudes to match those actions, _______________ _______________ theory attempts to explain why.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 74 REVIEW

74-1 What do social psychologists study? How do we tend to explain others' behavior and our own?

- *Social psychologists* use scientific methods to study how people think about, influence, and relate to one another. They study the social influences that explain why the same person will act differently in different situations.
- When explaining others' behavior, we may—especially if we come from an individualist Western culture—commit the *fundamental attribution error* (underestimating the influence of the situation and overestimating the effects of stable, enduring traits). When explaining our own behavior, we more readily attribute it to the influence of the situation.

74-2 How do attitudes and actions interact?

- *Attitudes* are feelings, often influenced by our beliefs, that predispose us to respond in certain ways.
- *Peripheral route persuasion* uses incidental cues (such as celebrity endorsement) to try to produce fast but relatively thoughtless changes in attitudes.
- *Central route persuasion* offers evidence and arguments to trigger thoughtful responses.
- When other influences are minimal, attitudes that are stable, specific, and easily recalled can affect our actions.
- Actions can modify attitudes, as in the *foot-in-the-door phenomenon* (complying with a large request after having agreed to a small request) and role playing (acting a social part by following guidelines for expected behavior).
- When our attitudes don't fit with our actions, *cognitive dissonance*

theory suggests that we will reduce tension by changing our attitudes to match our actions.

Multiple-Choice Questions

1. Claire has had several car accidents that she blames on other drivers. When her boyfriend has an accident, she is quick to blame his carelessness behind the wheel. Claire's difference in blame is due to

a. peripheral route persuasion.
b. cognitive dissonance.
c. the fundamental attribution error.
d. the foot-in-the-door phenomenon.
e. central route persuasion.

2. A feeling, often influenced by a belief, that predisposes one to respond in a particular way to people and events is known as

a. central route persuasion.
b. a role.
c. social psychology.
d. the foot-in-the-door phenomenon.
e. an attitude.

3. The discomfort we feel when our attitudes are not in line with our actions is called

a. cognitive dissonance.
b. the power of the situation.
c. the foot-in-the-door phenomenon.
d. role playing.
e. the fundamental attribution error.

Practice FRQs

1. Explain how central route persuasion and peripheral route persuasion could be used by your school's cafeteria to increase lunch sales.

Answer

1 point: Central route persuasion would use facts, such as the health benefits of eating certain foods, or the value-pricing of the available options, to influence the students to purchase the food. Page 771

1 point: Peripheral route persuasion would focus more on emotion and might attempt to display the food in a very appetizing way to create an impulse decision to purchase the food. Page 771

2. Using the guards in the Zimbardo prison simulation as your example, explain the following psychological concepts:

- Foot-in-the-door phenomenon
- Power of the situation
- Cognitive dissonance

(3 points)

Module **75 Conformity and Obedience**

LEARNING TARGETS

- 75-1 Describe *social contagion*, and explain how conformity experiments reveal the power of social influence.
- 75-2 Explain what Milgram’s obedience experiments teach us about the power of social influence.
- 75-3 Discuss what the social influence studies teach us about ourselves and the power we have as individuals.

Social psychology’s great lesson is the enormous power of social influence. This influence stems in part from social **norms**—rules for expected and acceptable behavior. At high school, jeans are the norm; on New York’s Wall Street or London’s Bond Street, business attire is expected. When we know how to act, how to groom, how to talk, life functions smoothly.

norms
understood rules for accepted and expected behavior. Norms prescribe “proper” behavior.

But sometimes social pressure moves people in dreadful directions. Isolated with others who share their grievances, dissenters may gradually become rebels, and rebels may become terrorists. Suicides, bomb threats, airplane hijackings, and mass shootings all have a curious tendency to come in clusters. After a mass killing, the probability of another such attack increases for the ensuing 13 days (Towers et al., 2015). Let’s examine the pull of these social strings. How strong are they? How do they operate? When do we break them?

Conformity: Complying With Social Pressures

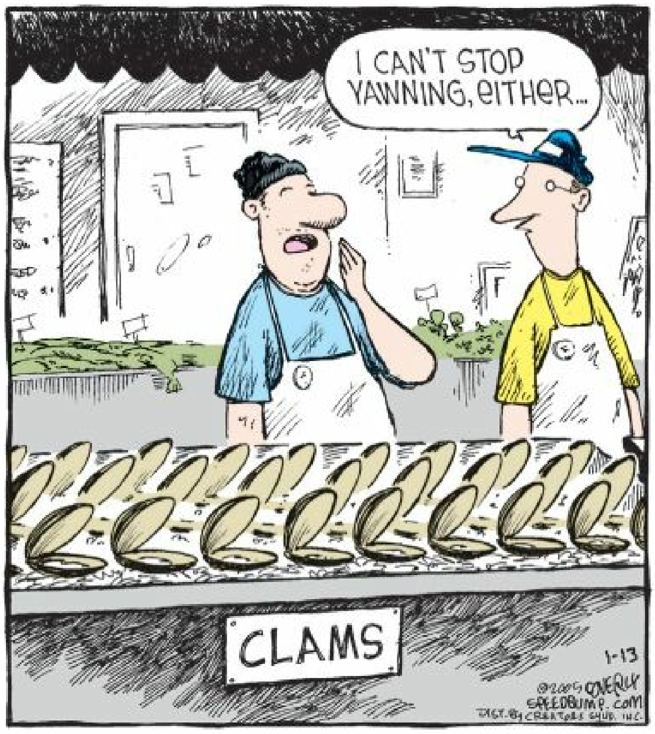
75-1 What is *social contagion*, and how do conformity experiments reveal the power of social influence?

Social Contagion

Fish swim in schools. Birds fly in flocks. And humans, too, tend to go with their group, to think what it thinks and do what it does. Behavior is contagious. If one of us yawns, laughs, coughs, scratches, stares at the sky, or checks our phone, others in our group will often do the same (Holle et al., 2012). Even just reading about yawning increases people's yawning (Provine, 2012), as perhaps you will notice? Yawn mimicry also occurs in other species—among chimpanzees, for example (Anderson et al., 2004)—and even across species: Dogs more often yawn after observing their owner yawn (Silva et al., 2012).

> “*Have you ever noticed how one example—good or bad—can prompt others to follow? How one illegally parked car can give permission for others to do likewise? How one racial joke can fuel another?*”
>
> *Marian Wright Edelman,* The Measure of Our Success, *1992*

Tanya Chartrand and John Bargh (1999) call this social contagion the *chameleon effect*, likening it to chameleon lizards' ability to take on the color of their surroundings. They captured it by having students work in a room alongside another person (actually a “confederate” working for the experimenters). Sometimes the confederates rubbed their own face. Sometimes they shook their foot. Sure enough, students tended to rub their face when with the face-rubbing person and shake their foot when with the foot-shaking person.



I CAN'T STOP YAWNING, EITHER...
CLAMS
1-13

SPEEDBUMP.COM
DIST. BY CREATORS SYND. INC.

© Dave Coverly/speedbump.com

Social contagion is not confined to behavior. We human chameleons also take on the emotional tones of those around us—their expressions, postures, inflections—and even their grammar (Ireland & Pennebaker, 2010). Just hearing someone reading a neutral text in either a happy- or sad-sounding voice creates *mood contagion* in listeners (Neumann & Strack, 2000).

Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Social contagion Laughter, like yawns, is infectious. That's what "Chewbacca Mom's" (Candace Payne's) viewers discovered after her spontaneous hilarity became, with 164 million views, Facebook Live's most watched 2016 video (tinyurl.com/ThatLaugh).

This natural mimicry enables us to *empathize*—to feel what others are feeling. This helps explain why we feel happier around happy people than around depressed people. It also helps explain why studies of groups of British workers have revealed *mood linkage*, or the sharing of moods (Totterdell et al., 1998). Empathic mimicking fosters fondness (Chartrand & van Baaren, 2009; Lakin et al., 2008). Perhaps you've noticed that when someone nods their head as you do and echoes your words, you feel a certain rapport and liking?

Social networks serve as contagious pathways for moods, such as happiness and loneliness, drug use, and even the behavior patterns that lead to obesity and sleep loss (Christakis & Fowler, 2009). On websites, positive ratings generate more positive ratings—a phenomenon called *positive herding* (Muchnik et al., 2013). In a massive experiment on the 2010 U.S. congressional election day, Facebook showed 61 million people a message that encouraged voting, with a link to a local voting place and a clickable “I voted” button. For some recipients, the messages also contained pictures of Facebook friends who had already voted. Those who received “tell your friends you voted” messages were slightly more likely to vote, and that difference generated an estimated 282,000 additional votes.

Suggestibility and mimicry sometimes lead to tragedy. In the eight days following the 1999 shooting rampage at Colorado’s Columbine High School, every U.S. state except Vermont experienced threats of copycat violence. Pennsylvania alone recorded 60 such threats (Cooper, 1999). Spikes in suicide rates sometimes follow a highly publicized suicide (Phillips et al., 1985, 1989). In the wake of screen idol Marilyn Monroe’s suicide on August 5, 1962, the number of suicides in the United States exceeded the usual August count by 200.

> “*When I see synchrony and mimicry—whether it concerns yawning, laughing, dancing, or aping—I see social connection and bonding.*”
>
> *Primatologist Frans de Waal, “The Empathy Instinct,” 2009*

What causes behavior clusters? Do people act similarly because of their influence on one another? Or because they are simultaneously exposed to the same events and conditions? Seeking answers to such questions, social psychologists have conducted experiments on conformity.

Conformity and Social Norms

Suggestibility and mimicry are subtle types of **conformity**—adjusting our behavior or thinking toward some group standard. To study conformity, Solomon Asch (1955) devised a simple test. Imagine yourself as a participant in a supposed study of visual perception. You arrive in time to take a seat at a table with five other people. The experimenter asks the group to state, one by one, which of three comparison lines is identical to a standard line. You see clearly that the answer is Line 2, and you wait your turn to say so. Your boredom begins to show when the next set of lines proves equally easy.

conformity

adjusting our behavior or thinking to coincide with a group standard.

Now comes the third trial, and the correct answer seems just as clear-cut (**Figure 75.1**). But the first person gives what strikes you as a wrong answer: “Line 3.” When the second person and then the third and fourth give the same wrong answer, you sit up straight and squint. When the fifth person agrees with the first four, you feel your heart begin to pound. The experimenter then looks to you for your answer. Torn between the unanimity voiced by the five others and the evidence of your own eyes, you feel tense and suddenly unsure. You hesitate before answering, wondering whether you should suffer the discomfort of being the oddball. What answer do you give?

Figure 75.1 Asch’s conformity experiments

Which of the three comparison lines is equal to the standard line?

What do you suppose most people would say after hearing five others say, “Line 3”? In this photo from one of Asch’s experiments, the student in the center shows the severe discomfort that comes from disagreeing with the responses of other group members (in this case, accomplices of the experimenter).

Flip It Video: Normative Social Influence

In Asch’s experiments, college students, answering questions alone, erred less than 1 percent of the time. But what happened when several others—confederates—answered incorrectly? Although most people told the truth even when others did not, Asch was disturbed by his result: More than one-third of the time, these “intelligent and well-meaning” college students were “willing to call white black” by going along with the group.

Sanne Berg/Getty Images

Tattoos: Yesterday’s nonconformity, today’s conformity? As tattoos become perceived as fashion conformity, their popularity may wane.

Later investigations have not always found as much conformity as Asch found, but they have revealed that we are more likely to conform when we

- are made to feel incompetent or insecure.

- are in a group with at least three people.
- are in a group in which everyone else agrees. (If just one other person disagrees, the odds of our disagreeing greatly increase.)
- admire the group's status and attractiveness.
- have not made a prior commitment to any response.
- know that others in the group will observe our behavior.
- are from a culture that strongly encourages respect for social standards.

Why do we so often think as others think and do as they do? Why, when asked controversial questions, are college students' answers more similar when they raise their hands and more diverse when they use anonymous electronic clickers (Stowell et al., 2010)? Why do we clap when others clap, eat as others eat, believe what others believe, say what others say, even see what others see?

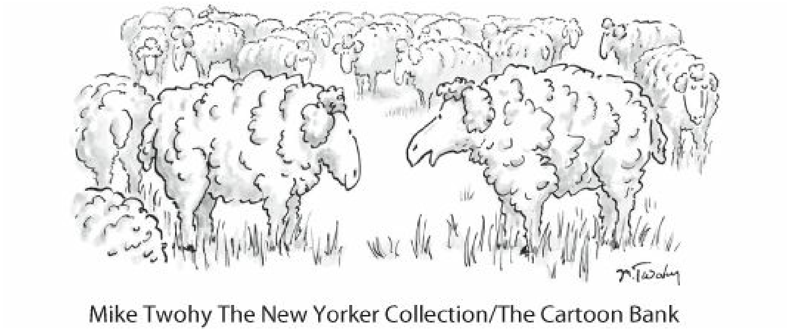
Frequently, we conform to avoid rejection or to gain social approval (Williams & Sommer, 1997). In such cases, we are responding to **normative social influence**. We are sensitive to social norms because the price we pay for being different can be severe. We need to belong. At other times, we conform because we want to be accurate. Groups provide information, and only an uncommonly stubborn person will never listen to others. When we accept others' opinions about reality, as when reading online movie and restaurant reviews, we are responding to **informational social influence**. As one female Welsh driver demonstrated in 2004, sometimes it pays to assume others are right and to follow their lead. She set a record for the longest distance driven on the wrong side of a British divided highway—30 miles, with only one minor sideswipe, before the motorway ran out and police were able to puncture her tires. The driver, who was intoxicated, later explained that she thought the hundreds of other drivers coming at her were all on the wrong side of the road (Woolcock, 2004).

normative social influence

influence resulting from a person's desire to gain approval or avoid disapproval.

informational social influence

influence resulting from one’s willingness to accept others’ opinions about reality.



Mike Twohy The New Yorker Collection/The Cartoon Bank

“I love the little ways you’re identical to everyone else.”

Is conformity bad or good? Conformity can be bad—leading people to agree with falsehoods or go along with bullying. Or it can be good—leading people to give more generously after observing others’ generosity (Nook et al., 2016). The answer also depends partly on our culturally influenced values. People in many Asian, African, and Latin American countries place a high value on collectivism (honoring group standards). Western Europeans and people in most English-speaking countries tend to prize individualism (giving priority to personal goals over group goals). Experiments across 17 countries have found lower conformity rates in individualist cultures (Bond & Smith, 1996). American university students, for example, tend to see themselves as less conforming than others (Pronin et al., 2007). We are, in our own eyes, individuals amid a crowd of sheep.

FYI

Like humans, migrating and herding animals conform for both informational and normative reasons (Claidière & Whiten, 2012). Following others is informative; compared with solo geese, a flock of geese migrates more accurately. (There is wisdom in the crowd.) And staying with the herd also sustains group membership.

Obedience: Following Orders

75-2 What do Milgram's obedience experiments teach us about the power of social influence?

Social psychologist Stanley Milgram (1963, 1974), a high school classmate of Philip Zimbardo and then a student of Solomon Asch, knew that people often give in to social pressures. But what about outright commands? Would they respond as did those who carried out Holocaust atrocities? (Some of Milgram's family members were Nazi concentration camp survivors.) To find out, he undertook what have become social psychology's most famous and controversial experiments (Benjamin & Simpson, 2009).

Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Stanley Milgram (1933–1984) This social psychologist's obedience experiments "belong to the self-understanding of literate people in our age" (Sabini, 1986).

Imagine yourself as one of the nearly 1000 people who took part in Milgram's 20 experiments. You respond to an ad for participants in a Yale University psychology study of the effect of punishment on learning. Professor Milgram's assistant asks you and another person to draw slips from a hat to see who will be the "teacher" and who will be the "learner." You draw a "teacher" slip (unknown to you, both slips say "teacher"). The supposed learner, a mild and submissive-seeming man, is led to an adjoining room and strapped into a chair. From the chair, wires run through the wall to your machine. You sit down in front of a shock machine and are given your task: Teach and then test the learner on a list of word pairs. If the learner gives a wrong answer, you are to flip a switch to deliver a brief electric shock. For the first wrong answer, you will flip the switch labeled “15 Volts—Slight Shock.” With each succeeding error, you will move to the next higher voltage. With each flip of a switch, lights flash and electronic switches buzz.

The experiment begins, and you deliver the shocks after the first and second wrong answers. If you continue, you hear the learner grunt when you flick the third, fourth, and fifth switches. After you activate the eighth switch (“120 Volts—Moderate Shock”), the learner cries out that the shocks are painful. After the tenth switch (“150 Volts—Strong Shock”), he begins shouting. “Get me out of here! I won’t be in the experiment anymore! I refuse to go on!” You draw back, but the stern experimenter prods you: “Please continue—the experiment requires that you continue.” You resist, but the experimenter insists, “It is absolutely essential that you continue,” or “You have no other choice, you *must* go on.”

If you obey, you hear the learner shriek in apparent agony as you continue to raise the shock level after each new error. After the 330-volt level, the learner refuses to answer and falls silent. Still, the experimenter pushes you toward the final, 450-volt switch. “Ask the question,” he says, “and if no correct answer is given, administer the next shock level.”

Would you follow the experimenter’s commands to shock someone? At what level would you refuse to obey? Before undertaking the experiments, Milgram asked nonparticipants what they would do. Most were sure they would stop soon after the learner first indicated pain, certainly before he shrieked in agony. Forty psychiatrists agreed with that prediction. Were the predictions accurate? Not even close. When Milgram conducted the experiment with other men aged 20 to 50, he was astonished. More than 60 percent complied fully—right up to the last switch. When he ran a new study, with 40 new “teachers” and a learner who complained of a “slight heart condition,” the results were similar. A full 65 percent of the new teachers obeyed the experimenter, right up to 450 volts (**Figure 75.2**). In 10 later studies, women obeyed at rates similar to men’s (Blass, 1999).

Figure 75.2 Milgram’s follow-up obedience experiment

In a repeat of the earlier experiment, 65 percent of the adult male “teachers” fully obeyed the experimenter’s commands to continue. They did so despite the “learner’s” earlier mention of a heart condition and despite hearing cries of protest after they administered what they thought were 150 volts and agonized protests after 330 volts.

Were Milgram’s results a product of the 1960s American mindset? *No.* When one researcher substantially repeated Milgram’s basic experiment, 70 percent of the participants complied up to the 150-volt point—only a slight reduction from Milgram’s 83 percent at that level (Burger, 2009). A Polish research team found 90 percent compliance to the same level (Dolin´ski et al., 2017). When a French reality TV show replicated Milgram’s study, 81 percent of the teachers, egged on by a cheering audience, obeyed and tortured a screaming victim (Beauvois et al., 2012).

Did Milgram’s teachers figure out the hoax—that no real shock was being delivered and the learner was in fact a confederate pretending to feel pain? Did they realize the experiment was really testing their willingness to comply with commands to inflict punishment? *No.* The teachers typically displayed genuine distress: They perspired, trembled, laughed nervously, and bit their lips.

Milgram's use of deception and stress triggered a debate over his research ethics. In his own defense, Milgram pointed out that, after the participants learned of the deception and actual research purposes, virtually none regretted taking part (though perhaps by then the participants had reduced their cognitive dissonance—the discomfort they felt when their actions conflicted with their attitudes). When 40 of the teachers who had agonized most were later interviewed by a psychiatrist, none appeared to be suffering emotional aftereffects. All in all, said Milgram, the experiments provoked less enduring stress than university students experience when facing and failing big exams (Blass, 1996). Other scholars, however, after delving into Milgram's archives, report that his debriefing was less extensive and his participants' distress greater than he had suggested (Nicholson, 2011; Perry, 2013). Critics have also speculated that participants may have been identifying with the researcher and his scientific goals rather than being blindly obedient (Haslam et al., 2014, 2016).

In later experiments, Milgram discovered some conditions that influence people's behavior. When he varied the situation, full obedience ranged from 0 to 93 percent. Obedience was highest when

- *the person giving the orders was close at hand and was perceived to be a legitimate authority figure.* Such was the case in 2005 when Temple University's basketball coach sent a 250-pound bench player, Nehemiah Ingram, into a game with instructions to commit "hard fouls." Following orders, Ingram fouled out in four minutes after breaking an opposing player's right arm.
- *the authority figure was supported by a powerful or prestigious institution.* Compliance was somewhat lower when Milgram dissociated his experiments from Yale University. People have wondered: Why, during the 1994 Rwandan Genocide, did so many Hutu citizens slaughter their Tutsi neighbors? It was partly because they were part of

"a culture in which orders from above, even if evil," were understood as having the force of law (Kamatali, 2014).

- *the victim was depersonalized or at a distance, even in another room.* Similarly, many soldiers in combat either have not fired their rifles at an enemy they could see, or have not aimed them properly. Such refusals to kill are rarer among soldiers operating long-distance artillery or aircraft weapons (Padgett, 1989). Those who kill from a distance—by operating remotely piloted drones—also suffer much less posttraumatic stress than do veterans of on-the-ground conflict (Miller, 2012).
- *there were no role models for defiance*. "Teachers" did not see any other participant disobey the experimenter.

AP® EXAM TIP

Three of the most famous research projects in psychology were done by social psychologists, and you've now read about them all. Be able to identify the major contributions of Zimbardo (from Module 74), Asch, and Milgram.

The power of legitimate, close-at-hand authorities was apparent among those who followed orders to carry out the Nazis' Holocaust atrocities. Obedience alone does not explain the Holocaust—anti-Semitic ideology produced eager killers as well (Fenigstein, 2015; Mastroianni, 2015). But obedience was a factor. In the summer of 1942, nearly 500 middle-aged German reserve police officers were dispatched to German-occupied Jozefow, Poland. On July 13, the group's visibly upset commander informed his recruits, mostly family men, of their orders. They were to round up the village's Jews, who were said to be aiding the enemy. Able-bodied men would be sent to work camps, and the rest would be shot on the spot.

Jeff Widener/AP Photo

Standing up for democracy Some individuals—roughly one in three in Milgram’s experiments—resist social coercion, as did this unarmed man in Beijing, by single-handedly challenging an advancing line of tanks the day after the 1989 Tiananmen Square student uprising was suppressed.

The commander gave the recruits a chance to refuse to participate in the executions. Only about a dozen immediately refused. Within 17 hours, the remaining 485 officers killed 1500 helpless women, children, and elderly, shooting them in the back of the head as they lay face down. Hearing the victims’ pleas, and seeing the gruesome results, some 20 percent of the officers did eventually dissent, managing either to miss their victims or to slip away and hide until the slaughter was over (Browning, 1992). In real life, as in Milgram’s experiments, those who resisted usually did so early, and they were the minority.

A different story played out in the French village of Le Chambon. There, villagers openly defied orders to cooperate with the “New Order”: They sheltered French Jews destined for deportation to Germany, and they sometimes helped them escape across the Swiss border. The villagers’ Protestant ancestors had themselves been persecuted, and their pastors taught them to “resist whenever our adversaries will demand of us obedience contrary to the orders of the Gospel” (Rochat, 1993). Ordered by police to give a list of sheltered Jews, the head pastor modeled defiance: “I don’t know of Jews, I only know of human beings.” At great personal risk, the people of Le Chambon made an initial commitment to resist. Throughout the long and terrible war, they suffered poverty and were punished for their disobedience. Still, supported by their beliefs, their role models, their interactions with one another, and their own initial acts, they remained defiant to the war’s end.

Lest we presume that obedience is always evil and resistance is always good, consider the heroic obedience of British soldiers who, in 1852, were traveling with civilians aboard the steamship *Birkenhead.* As they neared their South African port, the *Birkenhead* became impaled on a rock. To calm the passengers and permit an orderly exit of civilians on the three available lifeboats, soldiers who were not assisting the passengers or working the pumps lined up at parade rest. “Steady, men!” said their officer as the lifeboats pulled away. Heroically, no one frantically rushed to claim a lifeboat seat. As the boat sank, all were plunged into the sea, most to be drowned or devoured by sharks. For almost a century, noted James Michener (1978), “the Birkenhead drill remained the measure by which heroic behavior at sea was measured.”

Lessons From the Conformity and Obedience Studies

75-3 What do the social influence studies teach us about ourselves? How much power do we have as individuals?

How do the laboratory experiments on social influence relate to everyday life? How does judging the length of a line or flicking a shock switch relate to everyday social behavior? Recall from Module 6 that psychology’s experiments aim not to re-create the literal behaviors of everyday life but to capture and explore the underlying processes that shape those behaviors. Solomon Asch and Stanley Milgram devised experiments that forced a familiar choice: Do I adhere to my own standards, even when they conflict with the expectations of others?

In Milgram’s experiments and their modern replications, participants were torn. Should they respond to the pleas of the victim or the orders of the experimenter? Their moral sense warned them not to harm another, yet it also prompted them to obey the experimenter and to be a good research participant. With kindness and obedience on a collision course, obedience usually won.

> “*I was only following orders.*”
>
> *Adolf Eichmann, director of Nazi deportation of Jews to concentration camps*

These experiments demonstrated that strong social influences induce many people to conform to falsehoods or capitulate to cruelty. Milgram saw this as the fundamental lesson of this work: “Ordinary people, simply doing their jobs, and without any particular hostility on their part, can become agents in a terrible destructive process” (1974, p. 6).

Focusing on the end point—450 volts, or someone’s real-life violence—we can hardly comprehend the inhumanity. But Milgram did not entrap his teachers by asking them first to zap learners with enough electricity to make their hair stand on end. Using the foot-in-the-door technique, he instead began with a little tickle of electricity and escalated step by step. In the minds of those throwing the switches, the small action became justified, making the next act tolerable. So it happens when people succumb, gradually, to evil.

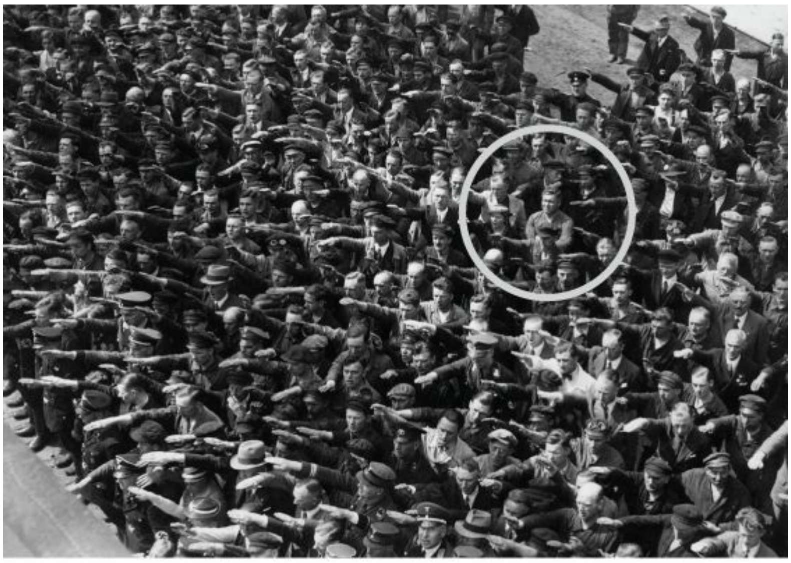
> “*All evil begins with 15 volts.*”
>
> *Philip Zimbardo, Stanford lecture, 2010*

In any society, great evils often grow out of people’s compliance with lesser evils. The Nazi leaders suspected that most German civil servants would resist shooting or gassing Jews directly, but they found them surprisingly willing to handle the paperwork of the Holocaust (Silver & Geller, 1978). Milgram found a similar reaction in his experiments. When he asked 40 men to administer the learning test while someone else did the shocking, 93 percent complied. Cruelty does not require devilish villains. All it takes is ordinary people corrupted by an evil situation. Ordinary students may follow orders to haze initiates into their group. Ordinary employees may follow orders to produce and market harmful products. Ordinary soldiers may follow orders to punish and then torture prisoners (Lankford, 2009).

In Jozefow and Le Chambon, as in Milgram’s experiments, those who resisted usually did so early. After the first acts of compliance or resistance, attitudes began to follow and justify behavior.

What have social psychologists learned about the power of the individual? *Social control* (the power of the situation) and *personal control* (the power of the individual) interact. Much as water dissolves salt but not sand, so rotten situations turn some people into bad apples while others resist (Johnson, 2007).

Some people do resist. When feeling pressured, some react by doing the opposite of what is expected (Brehm & Brehm, 1981). The power of one or two individuals to sway majorities is *minority influence* (Moscovici, 1985). In studies, one finding repeatedly stands out. When you are the minority, you are far more likely to sway the majority if you hold firmly to your position and don’t waffle. This tactic won’t make you popular, but it may make you influential, especially if your self-confidence stimulates others to consider why you react as you do. Even when a minority’s influence is not yet visible, people may privately develop sympathy for the minority position and rethink their views (Wood et al., 1994).



Sueddeutsche Zeitung Photo/Alamy

A minority of one To be August Landmesser, standing defiantly with arms folded as everyone else salutes their allegiance to the Nazi Party and Adolph Hitler, requires extraordinary courage. But sometimes such individuals have inspired others, demonstrating the power of minority influence.

> “*If evil is contagious, so is goodness.*”
>
> *Tweet from Pope Francis, 2017*

The powers of social influence are enormous, but so are the powers of the committed individual. Were this not so, communism would have remained an obscure theory, Christianity would be a small Middle Eastern sect, and Rosa Parks’ refusal to sit at the back of the bus would not have ignited the U.S. civil rights movement. Social forces matter. But individuals matter, too.

Check Your Understanding

Ask Yourself

- How have you found yourself conforming, or perhaps “conforming to nonconformity”? In what ways have you seen others identifying themselves with those of the same culture or subculture?

Test Yourself

- Despite her mother’s pleas to use a more ergonomic backpack, Antonia insists on trying to carry all of her books to school in an oversized purse the way her fashionable friends all seem to do. Antonia is affected by what type of social influence?
- Psychology’s most famous obedience experiments, in which most participants obeyed an authority figure’s demands to inflict presumed painful, dangerous shocks on an innocent participant, were conducted by social psychologist _______________ _______________.
- What types of situations have researchers found to be most likely to encourage obedience in participants?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 75 REVIEW

75-1 What is *social contagion*, and how do conformity experiments reveal the power of social influence?

- Social contagion (the chameleon effect), our tendency to unconsciously imitate others’ behavior, expressions, postures, inflections, and moods, is a form of *conformity*. Social networks serve as contagious pathways for moods, both good and bad.
- Solomon Asch and others have found that we are most likely to adjust our behavior or thinking to coincide with a group standard when (a) we feel incompetent or insecure, (b) our group has at least three people, (c) everyone else agrees, (d) we admire the group’s status and attractiveness, (e) we have not already committed to another response, (f) we know we are being observed, and (g) our culture encourages respect for social standards.
- We may conform to gain approval *(normative social influence)* or because we are willing to accept others’ opinions as new information *(informational social influence)*.

75-2 What do Milgram’s obedience experiments teach us about the power of social influence?

- Stanley Milgram’s experiments—in which people obeyed orders even when they thought they were harming another person—demonstrated that strong social influences can make ordinary people conform to falsehoods or give in to cruelty.
- Obedience was highest when (a) the person giving orders was nearby and was perceived as a legitimate authority figure, (b) the research was supported by a prestigious institution, (c) the victim was depersonalized or at a distance, and (d) there were no role models for defiance.

75-3 What do the social influence studies teach us about ourselves? How much power do we have as individuals?

- These experiments have demonstrated that strong social influences can make people conform to falsehoods or capitulate to cruelty. The power of the individual (personal control) and the power of the situation (social control) interact.
- A small minority that consistently expresses its views may sway the majority, as may even a single committed individual.

Multiple-Choice Questions

1. Which of the following is an example of conformity?

a. Malik has had a series of dogs over the years. Each has learned to curl up at his feet when he watches television.

b. Renee buys the same brand of sweatshirt that most of the kids in her school are wearing.

c. Jonah makes sure to arrive home before his curfew because he knows he will be grounded if he doesn't.

d. Yuri makes sure to arrive home before her curfew because she does not want her parents to be disappointed in her.

e. Terry cranks it up a notch during volleyball practice because the team captain has been on her case for not showing enough effort.

2. Jon does what his friends are doing and throws eggs at houses on Halloween, even though he knows that he should not. Jon's egg throwing is most likely due to

a. obedience.

b. normative social influence.

c. social contagion.

d. informational social influence.

e. the chameleon effect.

3. In Milgram's classic study on obedience, approximately what percentage of people delivered what they believed to be the maximum shock level?

a. One-tenth
b. One-half
c. One-third
d. One-fourth
e. Two-thirds

4. In Milgram’s studies, obedience to authority was highest when

a. the person receiving orders witnessed others defying the authority figure.
b. the person receiving orders wondered whether the person giving orders had legitimate authority.
c. the person supposedly receiving the shocks was physically near the person receiving orders.
d. the authority figure was from a prestigious institution.
e. the person receiving the orders was female.

Practice FRQs

1. Pedro’s high school has a dress code that prohibits the wearing of hoods, such as with sweatshirts or jackets. The principal stands in the hallway and tells kids wearing their hoods up to take them down. Most students, including Pedro, comply. One day, Pedro sees a group of older boys he admires sneak past the principal with their hoods up, and Pedro does the same. Explain the terms *obedience* and *conformity* in this scenario.

Answer

1 point: Obedience is following the orders of an authority figure. When Pedro does what he is told by the principal and puts his hood down, he is demonstrating obedience. ↩ Page 778

1 point: Conformity is adjusting our behavior or thinking to coincide with a group standard. When Pedro leaves his hood up, he is conforming to the standard set by the older boys. Page 776

2. Explain two specific reasons why Milgram’s study would not pass the ethical guidelines of an institutional review board today. (See Module 7 if you need a reminder.)

(2 points)

Module **76 Group Behavior**

Flip It Video: Social Facilitation and Social Loafing

LEARNING TARGETS

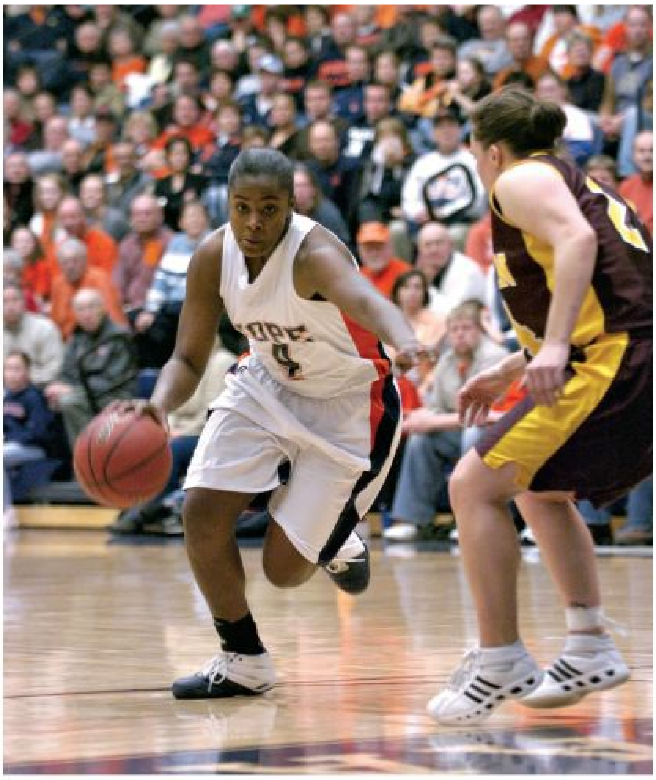
- 76-1 Describe how the presence of others influences our actions via social facilitation, social loafing, and deindividuation.
- 76-2 Explain how group interaction can enable group polarization.
- 76-3 Discuss the role the Internet plays in group polarization.
- 76-4 Discuss how group interaction can enable groupthink.
- 76-5 Describe how culture affects our behavior.

76-1 How does the presence of others influence our actions via social facilitation, social loafing, and deindividuation?

Imagine standing in a room holding a fishing pole. Your task is to wind the reel as fast as you can. On some occasions you wind in the presence of another participant, who is also winding as fast as possible. Will the other's presence affect your own performance?

In one of social psychology's first experiments, Norman Triplett (1898) reported that adolescents would wind a fishing reel faster in the presence of someone doing the same thing. Although a modern reanalysis revealed that the difference was modest (Stroebe, 2012), Triplett inspired later social psychologists to study how others' presence affects our behavior. Group influences operate both in simple groups—one person in the presence of another—and in more complex groups.

Social Facilitation



Hope College

Social facilitation Skilled athletes often find they are “on” before an audience. What they do well, they do even better when people are watching.

Triplett’s claim—of strengthened performance in others’ presence—is called **social facilitation**. But further studies revealed that the truth is more complicated: The presence of others strengthens our most *likely* response —the correct one on an easy task, an incorrect one on a difficult task (Guerin, 1986; Zajonc, 1965). Why? Because when others observe us, we become aroused, and this arousal amplifies our reactions. Thus, expert pool players who made 71 percent of their shots when alone made 80 percent when four people came to watch them (Michaels et al., 1982). Poor shooters, who made 36 percent of their shots when alone, made only 25 percent when watched.

social facilitation

improved performance on simple or well-learned tasks in the presence of others.

AP® EXAM TIP

As you work through this material, identify examples of group behavior in your own life. Then, compare your examples with a classmate's. This is a great way to make psychology come alive and to study effectively. If you apply these terms while reading the unit, it will be easier to identify the vocabulary later.

The energizing effect of an enthusiastic audience helps explain the home-team advantage that has shown up in studies of more than a quarter-million college and professional athletic events in various countries (Allen & Jones, 2014; Jamieson, 2010). Home teams win about 6 in 10 games, with the home advantage being greatest for teamwork-centered sports, such as soccer and basketball (Jones, 2015). For most sports, home cooking is best (see **Table 76.1**).

TABLE 76.1 Home Advantage in Team Sports

Sport	Years	Percentage of home games won
Nippon League Baseball	1998–2009	53.6
Major League Baseball	1903–2009	53.9
National Hockey League	1917–2009	55.7
International Rugby	1871–2009	56.9
National Football League	1966–2009	57.3
International Cricket	1877–	57.4

	2009	
National Basketball Association	1946–2009	60.5
Women’s National Basketball Association	2003-2009	61.7
English Premier League Soccer	1993–2009	63.0
NCAA Men’s Basketball	1947–2009	68.8
Major League Soccer	2002–2009	69.1

Data from Moskowitz & Wertheim, 2011.

The point to remember: What you do well, you are likely to do even better in front of an audience, especially a friendly audience. What you normally find difficult may seem all but impossible when you are being watched.

Social facilitation also helps explain a funny effect of crowding. Comedians know that a “good house” is a full one. What they may not know is that crowding triggers arousal. Comedy routines that are mildly amusing in an uncrowded room seem funnier in a densely packed room (Aiello et al., 1983; Freedman & Perlick, 1979). When seated close to one another, people like a friendly person even more and an unfriendly person even less (Schiffenbauer & Schiavo, 1976; Storms & Thomas, 1977). So, to increase the chances of a lively interaction at your next event, choose a room or set up seating that will just barely accommodate everyone.

Social Loafing

Social facilitation experiments test the effect of others’ presence on the performance of an individual task, such as shooting pool. But what happens when people perform as a group—say, in a team tug-of-war? Would you exert more, less, or the same effort as in a one-on-one match?

To find out, a University of Massachusetts research team asked blindfolded students “to pull as hard as you can” on a rope. When they fooled the students into believing three others were also pulling behind them, students exerted only 82 percent as much effort as when they knew they were pulling alone (Ingham et al., 1974). And consider what happened when blindfolded people seated in a group clapped or shouted as loudly as they could while hearing (through headphones) other people clapping or shouting loudly (Latané, 1981). When they thought they were part of a group effort, the participants produced about one-third less noise than when clapping or shouting “alone.”

This diminished effort is called **social loafing** (Jackson & Williams, 1988; Latané, 1981). Experiments in the United States, India, Thailand, Japan, China, and Taiwan have found social loafing on various tasks, though it was especially common among men in individualist cultures (Karau & Williams, 1993). What causes social loafing? When people act as part of a group, they may

- feel *less accountable* and therefore worry less about what others think.
- view their individual contributions as *dispensable* (Harkins & Szymanski, 1989; Kerr & Bruun, 1983).
- *overestimate* their own contributions, downplaying others’ actions (Schroeder et al., 2016).
- slack off (as you perhaps have observed on group assignments) if they share equally in the benefits, regardless of how much they contribute. Unless highly motivated and strongly identified with the group, people may *free ride* on others’ efforts.

social loafing

the tendency for people in a group to exert less effort when pooling their efforts toward attaining a common goal than when individually accountable.

Adie Bush/Getty Images

Working hard, or hardly working? In group projects, social loafing often occurs, as individuals free ride on the efforts of others.

Deindividuation

Lewis Whyld/ PA Wire/AP Images

Deindividuation During England’s 2011 riots and looting, rioters were disinhibited by social arousal and by the anonymity provided by darkness and their hoods and masks. Later, some of those arrested expressed bewilderment over their own behavior.

We’ve seen that the presence of others can arouse people (social facilitation), or it can diminish their feelings of responsibility (social loafing). But sometimes the presence of others does both. The uninhibited behavior that results can range from a food fight to vandalism or rioting. Perhaps you can recall following the crowd in yelling at a referee or opposing team? This process of losing self-awareness and self-restraint, called **deindividuation**, often occurs when group participation makes people both *aroused* and *anonymous*. Compared with identifiable women in a control group, New York University women dressed in depersonalizing Ku Klux Klan–style hoods delivered twice as much presumed electric shock to a victim (Zimbardo, 1970).

deindividuation

the loss of self-awareness and self-restraint occurring in group situations that foster arousal and anonymity.

Deindividuation thrives, for better or for worse, in many settings. The anonymity of online discussion boards and blog comment sections can unleash mocking or cruel words. Online bullies, who would never say “You’re the ugliest person I know” to someone’s face, will hide behind their anonymity. Tribal warriors who depersonalize themselves with face paints or masks are more likely than those with exposed faces to kill, torture, or mutilate captured enemies (Watson, 1973). When we shed self-awareness and self-restraint—whether in a mob, at a rock concert, at a ballgame, or at worship—we become more responsive to the group experience—bad or good. For a comparison of social facilitation, social loafing, and deindividuation, see **Table 76.2**.

TABLE 76.2 Behavior in the Presence of Others: Three Phenomena

Phenomenon	**Social context**	**Psychological effect of others’ presence**	**Behavioral effect**
Social facilitation	Individual being observed	Increased arousal	Amplified dominant behavior, such as doing better what one does well (or doing worse what is difficult)
Social loafing	Group projects	Diminished feelings of responsibility when not individually accountable	Decreased effort
Deindividuation	Group setting that fosters arousal and anonymity	Reduced self-awareness	Lowered self-restraint

✓ Check Your Understanding

Ask Yourself

- How have you experienced social loafing, such as with group projects?

Test Yourself

- What is social facilitation, and why is it more likely to occur with a well-learned task?
- People tend to exert less effort when working with a group than they would alone, which is called _______________ _______________.
- You are organizing a meeting of fiercely competitive political candidates. To add to the fun, friends have suggested handing out masks of the candidates' faces for supporters to wear. What phenomenon might these masks engage?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

* * *

We have examined the conditions under which the *presence* of others can motivate people to exert themselves or tempt them to free ride on the efforts of others, make easy tasks easier and difficult tasks harder, and enhance humor or fuel mob violence. Research also shows that *interacting* with others can similarly have both bad and good effects.

Group Polarization

76-2 How can group interaction enable group polarization?

We live in an increasingly polarized world. The Middle East is torn by warring factions. The European Union is struggling with nationalist divisions. In 1990, a one-minute speech in the U.S. Congress would enable you to guess the speaker’s party just 55 percent of the time; by 2009, partisanship was evident 83 percent of the time (Gentzkow et al., 2016). In 2016, for the first time in survey history, most U.S. Republicans and Democrats reported having “*very* unfavorable” views of the other party (Doherty & Kiley, 2016). And a record 77 percent of Americans perceived their nation as divided (Jones, 2016).

A powerful principle helps us understand our increasingly polarized world: The beliefs and attitudes we bring to a group grow stronger as we discuss them with like-minded others. This process, called **group polarization**, can have beneficial results, as when low-prejudice students become even more accepting while discussing racial issues. And it can be socially toxic, as when high-prejudice students who discuss racial issues become more prejudiced (Myers & Bishop, 1970; **Figure 76.1**). The repeated finding: Like minds polarize.

group polarization

the enhancement of a group’s prevailing inclinations through discussion within the group.

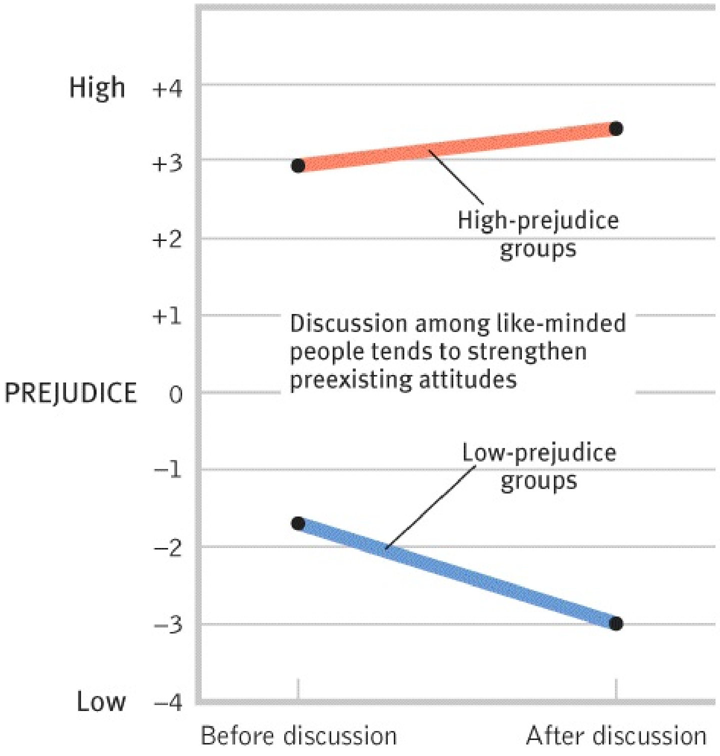


Figure 76.1

Figure 76.1 Group polarization

If a group is like-minded, discussion strengthens its prevailing opinions. Talking over racial issues increased prejudice in a high-prejudice group of high school students and decreased it in a low-prejudice group.

Analyses of terrorist organizations reveal that the terrorist mentality emerges slowly among people who share a grievance (McCauley, 2002; McCauley & Segal, 1987; Merari, 2002). As they interact in isolation (sometimes with other "brothers" and "sisters" in camps or in prisons), their views grow more and more extreme. Increasingly, they categorize the world as "us" against "them" (Chulov, 2014; Moghaddam, 2005). Knowing that group polarization occurs when like-minded people segregate, a 2006 U.S. National Intelligence estimate speculated that "the operational threat from self-radicalized cells will grow."

> “ *What explains the rise of fascism in the 1930s? The emergence of student*

> *radicalism in the 1960s? The growth of Islamic terrorism in the 1990s? . . . The unifying theme is simple:* When people find themselves in groups of like-minded types, they are especially likely to move to extremes. *[This] is the phenomenon of* group polarization.”
>
> *Cass Sunstein (2009)*

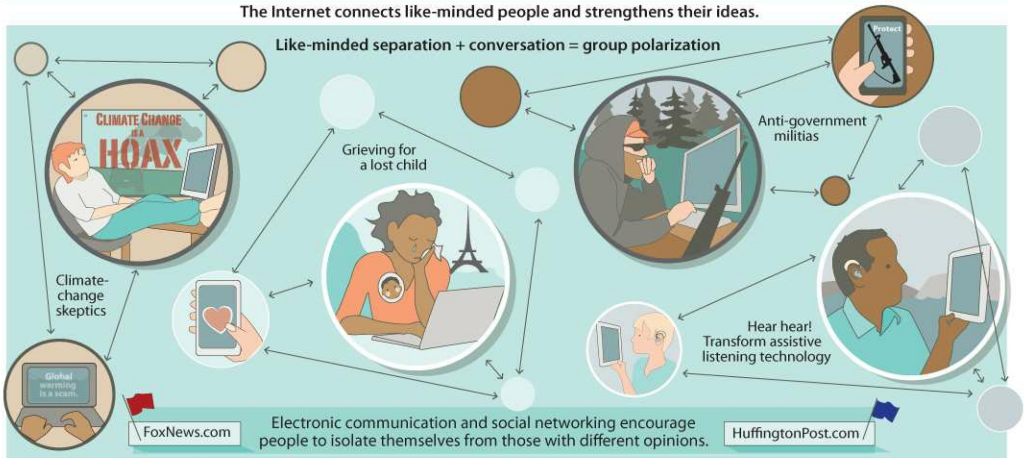
The Internet offers us a connected global world, yet also provides an easily accessible medium for group polarization. When I [DM] got my start in social psychology with experiments on group polarization, I never imagined the potential dangers, or the creative possibilities, of polarization in *virtual* groups. On the plus side, I can network with other advocates of accessibility for people with hearing loss. On the minus side, the Internet enables opinion bubbles: Progressives friend progressives and share links to sites that affirm their shared views. Conservatives connect with conservatives and likewise share conservative perspectives. With news feeds and retweets, we feed one another information—and misinformation—and click on content we agree with (Bakshy et al., 2015; Barberá et al., 2015). Thus, within the Internet’s echo chamber of the like-minded, views become more extreme. Suspicion becomes conviction. Disagreements with the other tribe can escalate to demonization. (For more on the Internet’s role in group polarization—toward ends that are good as well as bad—see Thinking Critically About: The Internet as Social Amplifier.)

> “*Dear Satan, thank you for having my Internet news feeds tailored especially for ME!*”
>
> *Comedian Steve Martin, 2016 tweet*

76-3 What role does the Internet play in group polarization?

Thinking Critically About:
The Internet as Social Amplifier

The Internet connects like-minded people and strengthens their ideas.



Like-minded separation + conversation = group polarization
CLIMATE CHANGE IS A HOAX
Climate-change skeptics
Global warming is a scam.
Grieving for a lost child
Protect
Anti-government militias
Hear hear! Transform assistive listening technology
FoxNews.com
HuffingtonPost.com

Electronic communication and social networking encourage people to isolate themselves from those with different opinions.

On Facebook and Twitter, we often share political content with like-minded others.[1]

White supremacists become more racist. Bullies become more abusive. And militia members become more violence-prone.

People find support online for their shared ideas and suspicions.

Peacemakers grow stronger in their convictions. Cancer survivors and bereaved parents strengthen shared perspectives of resilience. Social justice promoters become more committed.

Groupthink

76-4 How can group interaction enable groupthink?

Does group influence ever distort important national decisions? Consider the Bay of Pigs fiasco. In 1961, U.S. President John F. Kennedy and his advisers decided to invade Cuba with 1400 CIA-trained Cuban exiles. When the invaders were easily captured and quickly linked to the U.S. government, Kennedy wondered aloud, “How could I have been so stupid?”

> “*One of the dangers in the White House, based on my reading of history, is that you get wrapped up in groupthink and everybody agrees with everything, and there’s no discussion and there are no dissenting views.*”
>
> *Barack Obama, December 1, 2008, press conference*

Social psychologist Irving Janis (1982) studied the decision-making process leading to the ill-fated invasion. He discovered that the soaring morale of the recently elected president and his advisers fostered undue confidence. To preserve the good feeling, group members suppressed or self-censored their dissenting views, especially after President Kennedy voiced his enthusiasm for the scheme. Since no one spoke strongly against the idea, everyone assumed the support was unanimous. To describe this harmonious but unrealistic group thinking, Janis coined the term **groupthink**.

groupthink
the mode of thinking that occurs when the desire for harmony in a decision-making group overrides a realistic appraisal of alternatives.

Later studies showed that groupthink—fed by overconfidence, conformity, self-justification, and group polarization—contributed to other fiascos as well. Among them were the failure to anticipate the 1941 Japanese attack on Pearl Harbor; the escalation of the Vietnam war; the U.S. Watergate cover-up; the Chernobyl nuclear reactor accident (Reason, 1987); the U.S. space shuttle *Challenger* explosion (Esser & Lindoerfer, 1989); and the Iraq war, launched on the false idea that Iraq had weapons of mass destruction (U.S. Senate Intelligence Committee, 2004).

Despite the dangers of groupthink, two heads are often better than one. Knowing this, Janis also studied instances in which U.S. presidents and their advisers collectively made good decisions, such as when the Truman administration formulated the Marshall Plan, which offered assistance to Europe after World War II, and when the Kennedy administration successfully prevented the Soviets from installing missiles in Cuba. His conclusion? Groupthink is prevented when a leader—whether in government or in business—welcomes various opinions, invites experts' critiques of developing plans, and assigns people to identify possible problems. Just as the suppression of dissent bends a group toward bad decisions, open debate often shapes good ones. This is especially the case with diverse groups, whose varied perspectives often enable creative or superior outcomes (Nemeth & Ormiston, 2007; Page, 2007). Teams of smart people tend to surpass individual smart people at predicting political events (Mellers et al., 2015). None of us is as smart as all of us.

> “*If you have an apple and I have an apple and we exchange apples then you and I will still each have one apple. But if you have an idea and I have an idea and we exchange these ideas, then each of us will have two ideas.*”
>
> *Attributed to dramatist George Bernard Shaw, 1856–1950*

Cultural Influences

76-5 How does culture affect our behavior?

Compared with the narrow path taken by flies, fish, and foxes, the road along which environment drives us is wider. The mark of our species—nature’s great gift to us—is our ability to learn and adapt. We come equipped with a huge cerebral hard drive ready to receive cultural software.

Culture is the behaviors, ideas, attitudes, values, and traditions shared by a group of people and transmitted from one generation to the next (Brislin, 1988; Cohen, 2009). Human nature, noted Roy Baumeister (2005), seems designed for culture. We are social animals, but more. Wolves are social animals; they live and hunt in packs. Ants are incessantly social, never alone. But “culture is a better way of being social,” observed Baumeister. Wolves function pretty much as they did 10,000 years ago. We enjoy countless things that were unknown to our century-ago ancestors. Culture works.

culture

the enduring behaviors, ideas, attitudes, values, and traditions shared by a group of people and transmitted from one generation to the next.

Other animals exhibit smaller kernels of culture. Chimpanzees sometimes invent customs—using leaves to clean their bodies, slapping branches to get attention, and doing a “rain dance” by slowly displaying themselves at the start of rain—and pass them on to their peers and offspring (Whiten et al., 1999). Culture supports survival and reproduction by transmitting learned behaviors that give a group an edge. But human culture does more.

Thanks to our culture’s mastery of language, we humans enjoy the *preservation of innovation.* Within the span of this day, we have used

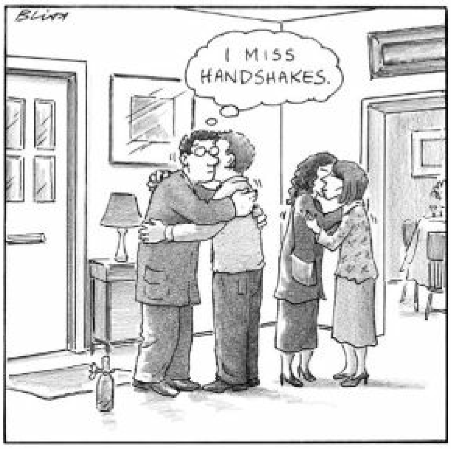
Google, smart phones, digital hearing technology [DM], and a GPS running watch [ND]. On a grander scale, we have culture's accumulated knowledge to thank for the last century's 30-year extension of the average human life expectancy in many countries. Moreover, culture enables an efficient *division of labor*. Although two lucky people get their name on this book (which transmits accumulated cultural wisdom), the product actually results from the coordination and commitment of a team of gifted people, no one of whom could produce it alone.

Across cultures, we differ. But beneath differences is our great similarity—our capacity for culture. Culture transmits the customs and beliefs that enable us to communicate, to exchange money for things, to play, to eat, and to drive with agreed-upon rules and without crashing into one another.

Variation Across Cultures

We see our adaptability in cultural variations among our beliefs and our values, in how we nurture our children and bury our dead, and in what we wear (or whether we wear anything at all). We are ever mindful that the worldwide readers of this book are culturally diverse. You and your ancestors reach from Asia to Africa.

Riding along with a unified culture is like biking with the wind: As it carries us along, we hardly notice it is there. When we try biking *against* the wind we feel its force. Face-to-face with a different culture, we become aware of the cultural winds. Visiting Europe, most North Americans notice the smaller cars, the left-handed use of the fork, the uninhibited attire on the beaches. Stationed in Iraq, Afghanistan, and Kuwait, American and European soldiers alike realized how liberal their home cultures were. Arriving in North America, visitors from Japan and India struggle to understand why so many people wear their dirty street shoes in the house.



I MISS HANDSHAKES.

The New Yorker Collection, 2010, Harry Bliss, from cartoonbank.com. All Rights Reserved

But humans in varied cultures nevertheless share some basic moral ideas. Even before they can walk, babies prefer helpful people over naughty ones (Hamlin et al., 2011). Worldwide, people prize honesty, fairness, and kindness (McGrath, 2015). Yet each cultural group also evolves its own norms. The British have a norm for orderly waiting in line. Many South Asians use only the right hand for eating. Sometimes social expectations seem oppressive: "Why should it matter how I dress?" Yet, norms—how to greet, how to eat—grease the social machinery.

When cultures collide, their differing norms often befuddle. Should we greet people by shaking hands, bowing, or kissing each cheek? Knowing what sorts of gestures and compliments are culturally appropriate, we can relax and enjoy one another without fear of embarrassment or insult.

When we don't understand what's expected or accepted, we may experience *culture shock.* People from Mediterranean cultures have perceived northern Europeans as efficient but cold and preoccupied with punctuality (Triandis, 1981). People from time-conscious Japan—where bank clocks keep exact time, pedestrians walk briskly, and postal clerks fill requests speedily—have found themselves growing impatient when visiting Indonesia, where the pace of life is more leisurely (Levine & Norenzayan, 1999). Someone from the European community, which requires 20 paid vacation days each year, may also experience culture shock when working in the United States, which does not guarantee workers any paid vacation (Ray et al., 2013).

Variation Over Time

Like biological creatures, cultures vary and compete for resources, and thus evolve over time (Mesoudi, 2009). Consider how rapidly cultures may change. English poet Geoffrey Chaucer (1342–1400) is separated from a modern Briton by only 25 generations, but the two would have great difficulty communicating. At the beginning of the last century, your ancestors lived in a world without cars, radio broadcasting, or widespread electric power and light. In the thin slice of history since 1960, most Western cultures have changed with astonishing speed. Middle-class people enjoy the convenience of air-conditioned housing, online shopping, anywhere-anytime electronic communication, and—enriched by doubled per-person real income—eating out more than twice as often as did their grandparents back in the culture of 1960. Many people now enjoy expanded human rights. And with greater economic independence, today's women more often marry for love and less often endure abusive relationships.

But some changes seem not so wonderfully positive. Had you fallen asleep in the United States in 1960 and awakened today, you would open your eyes to a culture with more depression and more economic inequality. You would also find North Americans—like their counterparts in Britain, Australia, and New Zealand—spending more hours at work, fewer hours with friends and family, and fewer hours asleep (BLS, 2011; Putnam, 2000).

Whether we love or loathe these changes, we cannot fail to be impressed by their breathtaking speed. And we cannot explain them by changes in the human gene pool, which evolves far too slowly to account for high-speed cultural transformations. Cultures vary. Cultures change. And cultures shape our lives.

✓ Check Your Understanding

Ask Yourself

- How have you been influenced by group polarization in your online activities?

Test Yourself

- When like-minded groups discuss a topic, and the result is the strengthening of the prevailing opinion, this is called _______________ _______________.
- When a group's desire for harmony overrides its realistic analysis of other options, _______________ has occurred.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 76 REVIEW

76-1 How does the presence of others influence our actions via social facilitation, social loafing, and deindividuation?

- In *social facilitation,* the mere presence of others arouses us, improving our performance on easy or well-learned tasks but decreasing it on difficult ones.
- In *social loafing,* participating in a group project makes us feel less responsible, and we may free ride on others' efforts.
- When the presence of others both arouses us and makes us feel anonymous, we may experience *deindividuation*—loss of self-awareness and self-restraint.

76-2 How can group interaction enable group polarization?

- In *group polarization,* group discussions with like-minded others strengthen members' prevailing beliefs and attitudes.

76-3 What role does the Internet play in group polarization?

- Internet communication magnifies the effect of connecting like-minded people, for better and for worse. People find support, which strengthens their ideas, but also often isolation from those with different opinions. Separation plus conversation may thus lead to group polarization.

76-4 How can group interaction enable groupthink?

- *Groupthink* is driven by a desire for harmony within a decision-making group, overriding realistic appraisal of alternatives.
- Group leaders can harness the benefits of group interaction by assigning people to identify possible problems, and by welcoming various opinions and expert critique.

76-5 How does culture affect our behavior?

- A *culture* is a set of behaviors, ideas, attitudes, values, and traditions shared by a group and transmitted from one generation to the next.
- Cultures differ across time and space.

Multiple-Choice Questions

1. Maggie is an excellent hockey player, and she is playing in the final hockey game of her high school career. The cheering of the fans causes her to score three goals in the game, a record for her. The most likely explanation for her performance is

a. social loafing.
b. group behavior.
c. social facilitation.
d. deindividuation.
e. group polarization.

2. Following a natural disaster, it is not uncommon for large groups of people to loot stores and take far more than they might need to help them survive the situation. This behavior is best explained by the concept of

a. culture.
b. social facilitation.
c. groupthink.
d. deindividuation.
e. group polarization.

3. Marie disagrees with the answer her math review group comes up with. She does not voice her own answer because she does not want to go against the group. Marie is being affected by

a. group polarization.
b. groupthink.
c. social loafing.

d. social facilitation.
e. cultural influences.

4. The enduring behaviors, ideas, attitudes, values, and traditions shared by a group of people and transmitted from one generation to the next is known as

a. deindividuation.
b. groupthink.
c. social facilitation.
d. culture.
e. social loafing.

Practice FRQs

1. Describe the four possible causes of social loafing.

Answer

1 point: People acting as part of a group feel less accountable. Page 785

1 point: Group members may view their individual contributions as dispensable. Page 785

1 point: People in a group may overestimate their own efforts, not considering how much others are contributing. Page 785

1 point: Unless highly motivated and strongly identified with the group, people may free ride on others' efforts. Page 785

2. Anonymous reviews of restaurants tend to be more negative than those where the name of the reviewer is attached. Explain why this is, using the following terms: *deindividuation* and *group polarization.*

(2 points)

Module **77 Prejudice and Discrimination**

LEARNING TARGETS

- **77-1 Define *prejudice*, and describe how explicit and implicit prejudice differ.**
- **77-2 Discuss the groups that are frequent targets of prejudice.**
- **77-3 Discuss some social, emotional, and cognitive roots of prejudice, and some ways to eliminate prejudice.**

77-1 What is *prejudice?* How do explicit and implicit prejudice differ?

Social psychology studies how we think about and influence one another, and also how we *relate* to one another. What causes people sometimes to hate and harm, and other times to love and help one another? And when destructive conflicts arise, how can we move toward a just peace? In this module and the next, we ponder insights into *antisocial* relations gleaned by researchers who have studied prejudice and aggression.

Prejudice means “prejudgment.” It is an unjustifiable and usually negative *attitude* toward a group and its members—who often are people of a particular racial or ethnic group, gender, sexual orientation, or belief system. You may recall that *attitudes* are feelings, influenced by beliefs, that predispose us to act in certain ways. In prejudice, the ingredients in this three-part mixture are

prejudice

an unjustifiable (and usually negative) attitude toward a group and its members. Prejudice generally involves stereotyped beliefs, negative feelings, and a predisposition to discriminatory action.

- *negative emotions,* such as hostility or fear.
- **stereotypes**, which are generalized beliefs about a group of people. Our stereotypes sometimes reflect reality. If you presume that young men tend to drive faster than elderly women, you may be right. But stereotypes often overgeneralize or exaggerate—as when liberals and conservatives overestimate the extremity of the other’s views, or Christians and atheists misperceive each other’s values (Graham et al., 2012; Simpson & Rios, 2016).
- *a predisposition to* **discriminate**—*to act in negative and unjustifiable ways toward members of the group.* Sometimes discrimination is blatant. Other times it is more subtle, taking the form of *microaggressions,* such as race-related traffic stops, a reluctance to choose a train seat next to someone of a different race, or longer Uber wait times and less Airbnb acceptance for people with African-American names (Edelman et al., 2017; Ge et al., 2016; Wang, J. et al., 2011).

stereotype

a generalized (sometimes accurate but often overgeneralized) belief about a group of people.

discrimination

unjustifiable negative behavior toward a group and its members.

Prejudice is a negative *attitude. Ethnocentrism*—assuming the superiority of one’s ethnic group—is one example of prejudice. To believe that a person of another ethnicity is somehow inferior or threatening, and to feel dislike for that person, is to be prejudiced. Discrimination is a negative *behavior.* To pass over that person on a dating site, or to reject that person as a job candidate, is to discriminate.

Explicit and Implicit Prejudice

Again and again, we have seen that our brain processes thoughts, memories, and attitudes on two different tracks. Sometimes that processing is *explicit*—on the radar screen of our awareness. More often, it is *implicit*—an unthinking knee-jerk response operating below the radar, leaving us unaware of how our attitudes are influencing our behavior. In 2015, the U.S. Supreme Court, in upholding the Fair Housing Act, recognized implicit bias research, noting that "unconscious prejudices" can cause discrimination even when people do not consciously intend to discriminate.

> "*We're also guarding against the subtle impulse to call Johnny back for a job interview but not Jamal.*"
>
> *President Barack Obama, funeral for Clementa Pinkney, 2015*

Psychologists study implicit prejudice by

- ***Testing for unconscious group associations:*** Tests in which people quickly pair a person's image with a trait demonstrate that even people who deny any racial prejudice may harbor negative associations (Banaji & Greenwald, 2013). Millions of people have taken the Implicit Association Test (at Implicit.Harvard.edu). Although the test is useful for studying automatic prejudice, critics question its reliability and caution against using it to assess or label individuals (Oswald et al., 2013, 2015). Defenders counter that implicit biases predict behaviors ranging from simple acts of friendliness to the evaluation of work quality (Greenwald et al., 2015).
- ***Considering unconscious patronization:*** In one experiment, White university women assessed flawed student essays they believed had been written by either a White or a Black student. The women gave low evaluations, often with harsh comments, to the essays supposedly written by a White student. When the same essay was attributed to a Black student, their assessment was more positive (Harber, 1998). Did

the evaluators calibrate their evaluations to their racial stereotypes, leading to less exacting standards and a patronizing attitude? In real-world evaluations, such low expectations and the resulting "inflated praise and insufficient criticism" could hinder minority student achievement, the researcher noted.

- ***Monitoring reflexive bodily responses:*** Even people who consciously express little prejudice may give off telltale signals as their body responds selectively to an image of a person from another ethnic group. Neuroscientists can detect signals of implicit prejudice in the viewer's facial-muscle responses and in the activation of the emotion-processing amygdala (Cunningham et al., 2004; Eberhardt, 2005; Stanley et al., 2008).

AP® EXAM TIP

It's worth spending a little time focusing on the distinction between *discrimination, prejudice,* and *stereotype.* They are related, but different. Be able to distinguish them in examples.

KAMIL KRZACZYNSKI/EPA/Newscom

Homegrown terrorism In the 16 years following the terror of September 11, 2001, many Americans feared attacks from foreign terrorists. Yet since that time, attacks by homegrown White supremacists and other non-Muslim extremists were nearly twice as likely (Shane, 2015)—as when a neo-Nazi slaughtered six people in a 2012 shooting at a Wisconsin Sikh temple.

Targets of Prejudice

77-2 What groups are frequent targets of prejudice?

Racial and Ethnic Prejudice

Americans’ expressed racial attitudes have changed dramatically in the last half-century. Support for interracial dating between Blacks and Whites, for example, has increased dramatically, from a 48 percent approval rate in 1987 to 86 percent in 2012 (Pew, 2012; see also **Figure 77.1**). Similarly, 4 percent of Americans approved of “marriage between Blacks and Whites” in 1958, but 87 percent approved in 2013 (Newport, 2013). Six in ten Americans—double the number in most European countries—agree that “an increasing number of people of many different races, ethnic groups, and nationalities in our country makes it a better place to live” (Drake & Poushter, 2016).

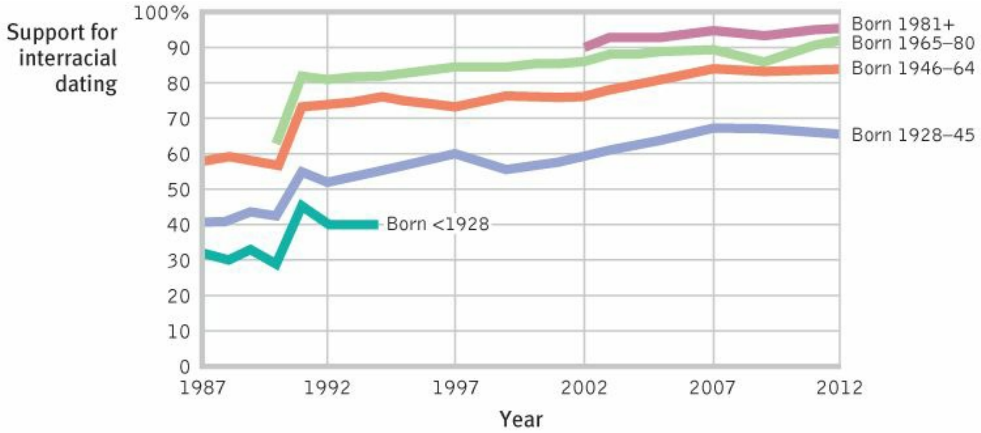


Figure 77.1
Myers/DeWall, *Myers’ Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from Pew, 2012.

Figure 77.1 Prejudice over time

Over the last quarter-century, Americans have increasingly approved of interracial dating, with each successive generation expressing more approval.

Yet as blatant interracial prejudice wanes, *subtle* prejudice lingers. People with darker skin tones experience greater criticism and accusations of immoral behavior (Alter et al., 2016). In one study of White medical students and residents, 1 in 3 believed “black people’s skin is thicker than white people’s skin,” which led them to make harmful treatment recommendations (Hoffman et al., 2016). And although many people *say* they would feel upset with someone making racist or homophobic slurs, they respond indifferently when they actually hear prejudice-laden language (Kawakami et al., 2009).

> “*Unhappily, the world has yet to learn how to live with diversity.*”
>
> *Pope John Paul II, Address to the United Nations, 1995*

Other studies reveal prejudice that is not just subtle, but unconscious (implicit). For example, in an Implicit Association Test, 9 in 10 White respondents took longer to identify pleasant words (such as *peace* and *paradise*) as “good” when presented with Black-sounding names (such as *Latisha* and *Darnell*) rather than with White-sounding names (such as *Katie* and *Ian*). Moreover, people who more quickly associate good things with White names or faces also are the quickest to perceive anger and apparent threat in Black faces (Hugenberg & Bodenhausen, 2003). A greater association of pleasant words with the racial terms “White” than “Black” has also been observed in more than 800 billion Internet words (Caliskan et al., 2017). In the 2008 U.S. presidential election, those demonstrating explicit *or* implicit prejudice were less likely to vote for candidate Barack Obama. His election in turn served to reduce implicit prejudice (Bernstein et al., 2010; Payne et al., 2010; Stephens-Davidowitz, 2014).

> “*If we can’t help our latent biases, we can help our behavior in response to those instinctive reactions, which is why we work to design systems and processes that overcome that very human part of us all.*”
>
> *U.S. FBI Director James B. Comey, “Hard Truths: Law Enforcement and Race,” 2015*

Our perceptions can also reflect implicit bias. In 1999, Amadou Diallo was accosted as he approached his apartment house doorway by police officers looking for a rapist. When he pulled out his wallet, the officers, perceiving a gun, riddled his body with 19 bullets from 41 shots. In one analysis of 59 unarmed suspect shootings in Philadelphia over seven years, 49 involved the misidentification of an object (such as a cell phone) or movement (such as pants tugging). Black suspects were more than twice as likely to be misperceived as threatening, even by Black officers (Blow, 2015). During 2015–2016, African Americans, who are 13 percent of the U.S. population, were nearly 40 percent of the unarmed people shot and killed by police (*Washington Post*, 2017).

To better understand such tragic shootings of unarmed, innocent people, two research teams simulated the situation (Correll et al., 2007, 2015; Plant & Peruche, 2005; Sadler et al., 2012). They asked viewers to press buttons quickly to “shoot” or not shoot men who suddenly appeared on screen. Some of the onscreen men held a gun. Others held a harmless object, such as a flashlight or bottle. People (both Blacks and Whites, and police officers) more often shot Black men holding the harmless object. Priming people with a flashed Black face rather than a White face also made them more likely to misperceive a flashed tool as a gun (**Figure 77.2**). Fatigue, which diminishes one’s conscious control and increases automatic reactions, amplifies racial bias in decisions to shoot (Ma et al., 2013).

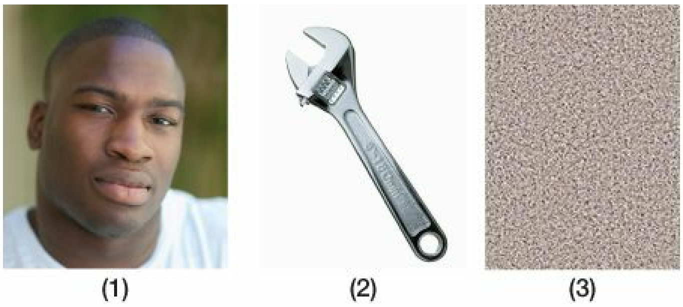

Figure 77.2
Myers/DeWall, *Myers’ Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 77.2 Race primes perceptions

In experiments by Keith Payne (2006), people viewed (1) a White or Black face, immediately followed by (2) a flashed gun or hand tool, which was then followed by (3) a masking screen. Participants were more likely to misperceive a tool as a gun when it was preceded by a Black rather than White face.

Gender Prejudice

Overt gender prejudice has declined sharply. The one-third of Americans who in 1937 told Gallup pollsters that they would vote for a qualified woman whom their party nominated for president soared to 95 percent in 2012 (Jones, 2012; Newport, 1999). Although women worldwide still represent nearly two-thirds of illiterate adults, and 30 percent have experienced intimate partner violence, 65 percent of all people now say it is very important that women have the same rights as men (UN, 2015; WHO, 2016; Zainulbhai, 2016).

> “*Until I was a man, I had no idea how good men had it at work. . . . The first time I spoke up in a meeting in my newly low, quiet voice and noticed that sudden, focused attention, I was so uncomfortable that I found myself unable to finish my sentence.*”
>
> *Thomas Page McBee, 2016, after transitioning from female to male*

Nevertheless, both implicit and explicit gender prejudice and discrimination persist. In Western countries, we pay more to those (usually men) who care for our streets than to those (usually women) who care for our children. Gender bias even applies to beliefs about intelligence: Despite equality between the sexes in intelligence scores, people have tended to perceive their fathers as more intelligent than their mothers and their sons as brighter than their daughters (Furnham, 2016).

Rex Features via AP Images

When tragedy triggers a national response Does implicit bias research—which is now being integrated into both police and corporate diversity training programs—help us understand the 2013 death of Trayvon Martin (shown here 7 months before he was killed)? As he walked alone to his father's fiance's house in a gated Florida neighborhood, a suspicious resident started following him. A confrontation led to the unarmed Martin being shot. Martin's death sparked public outrage related to racism, gun control, and social justice. Commentators wondered: Had Martin been an unarmed White teen, would he have been perceived and treated the same way?

Unwanted female infants are no longer left out on a hillside to die of exposure, as was the practice in ancient Greece. Yet the normal male-to-female newborn ratio (105-to-100) hardly explains the world's estimated 163 million (say that number slowly) "missing women" (Hvistendahl, 2011). In many places, sons are valued more than daughters. In India, there are 3.5 times more Google searches asking how to conceive a boy than how to conceive a girl (Stephens-Davidowitz, 2014). With scientific testing that enables sex-selective abortions, some countries are experiencing a shortfall in female births. India's newborn sex ratio was recently 112 boys for every 100 girls. China's has been 111 to 100—despite China's declaring sex-selective abortions—gender genocide—a criminal offense (CIA, 2014). With under-age-20 males exceeding females by 32 million, many Chinese bachelors will be unable to find mates (Zhu et al., 2009). A shortage of women also contributes to increased crime, violence, prostitution, and trafficking of women (Brooks, 2012).

LGBTQ Prejudice

In most of the world, gay and lesbian people cannot openly and comfortably disclose who they are and whom they love (Katz-Wise & Hyde, 2012; UN, 2011). Although by 2016 two dozen countries had allowed same-sex marriage, dozens more had laws criminalizing same-sex relationships. Cultural variation is enormous—ranging from the 98 percent in Ghana who say that "homosexuality is morally unacceptable" to 6 percent in Spain (Pew, 2014). Worldwide, anti-gay attitudes are most common among men, older adults, and those who are unhappy, unemployed, and less educated (Haney, 2016; Jäckle & Wenzelburger, 2015).

Explicit anti-gay prejudice, though declining in Western countries, persists. When experimenters sent thousands of responses to employment ads, those whose resumes included "Treasurer, Progressive and Socialist Alliance" received more replies than did resumes that specified "Treasurer, Gay and Lesbian Alliance" (Agerstro..m et al., 2012; Bertrand & Mullainathan, 2003; Drydakis, 2009). Other evidence has appeared in national surveys of LGBTQ Americans:

- 39 percent reported having been "rejected by a friend or family member" because of their sexual orientation or gender identity (Pew, 2013a).
- 58 percent reported being "subject to slurs or jokes" (Pew, 2013a).
- 80 percent of LGBTQ adolescents reported sexual orientation-related harassment in the prior year (GLSEN, 2012). Gays and lesbians are also America's most at-risk group for hate crimes (Sherman, 2016).

Do attitudes and practices that label, disparage, and discriminate against gay and lesbian people increase their risk of psychological disorder and ill health? In U.S. states without protections against LGBTQ hate crime and discrimination, gay and lesbian people experience substantially higher rates of depression and related disorders, even after controlling for income and education differences. In communities where anti-gay prejudice is high, so are gay and lesbian suicide and cardiovascular deaths. In 16 states that banned same-sex marriage between 2001 and 2005, gays and lesbians (but not heterosexuals) experienced a 37 percent increase in depressive disorder rates, a 42 percent increase in alcohol use disorder, and a 248 percent increase in generalized anxiety disorder. Meanwhile, gays and lesbians in other states did not experience increased psychiatric disorders (Hatzenbuehler, 2014).

Belief Systems Prejudice

In the aftermath of the 9/11 terrorist attacks, the Iraq and Afghanistan wars, and the rise of terrorist groups such as ISIS, many Americans have developed irrational fear and anger directed toward all Muslims (and all those they *think* might be Muslim). As a result, 48 percent of Muslim Americans have reported personally experiencing discrimination in the last year—more than double the average among U.S. Jews, Catholics, and Protestants (Gallup, 2017). As opposition to Islamic mosques and immigration has flared, one observer noted that "Muslims are one of the last minorities in the United States that it is still possible to demean openly" (Kristof, 2010; Lyons et al., 2010).

Roots of Prejudice

77-3 What are some social, emotional, and cognitive roots of prejudice, and what are some ways to eliminate prejudice?

Prejudice springs from a culture’s divisions, the heart’s passions, and the mind’s natural workings.

Social Inequalities and Divisions

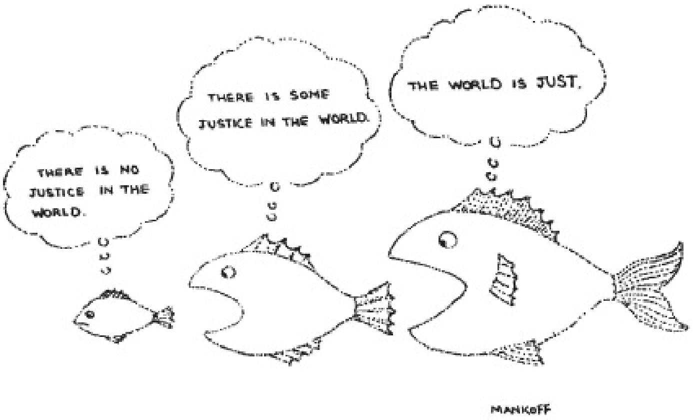
Flip It Video: Ingroup and Outgroup Bias

When some people have money, power, and prestige and others do not, the “haves” usually develop attitudes that justify things as they are. The **just-world phenomenon** reflects an idea we commonly teach our children—that good is rewarded and evil is punished. From this it is but a short and sometimes automatic leap to assume that those who succeed must be good and those who suffer must be bad. Such reasoning enables the rich to see both their own wealth and the poor’s misfortune as justly deserved. When slavery existed in the United States, slaveholders perceived slaves as innately lazy, ignorant, and irresponsible—as having the very traits that justified enslaving them. Stereotypes rationalize inequalities.

just-world phenomenon

the tendency for people to believe the world is just and that people therefore get what they deserve and deserve what they get.

Victims of discrimination may react with either self-blame or anger (Allport, 1954). Either reaction can feed others’ prejudice through the classic *blame-the-victim* dynamic. Do the circumstances of poverty breed a higher crime rate? If so, that higher crime rate can be used to justify discrimination against those who live in poverty.



THERE IS NO JUSTICE IN THE WORLD.
THERE IS SOME JUSTICE IN THE WORLD.
THE WORLD IS JUST.
MANKOFF

Robert Mankoff The New Yorker Collection/The Cartoon Bank

Dividing the world into “us” and “them” can entail conflict, racism, and war, but it also provides the benefits of communal solidarity. Thus, we cheer for our groups, kill for them, die for them. Indeed, we define who we are—our *social identity*—partly in terms of our groups (Greenaway et al., 2016; Hogg, 1996, 2006; Turner, 1987, 2007). When Ian identifies himself as a man, an Aussie, a University of Sydney student, a Catholic, and a MacGregor, he knows who he is, and so do we. Mentally drawing a circle defines “us,” the **ingroup**. But the social definition of who we are also states who we are not. People outside that circle are “them,” the **outgroup**. An **ingroup bias**—a favoring of our own group—soon follows. In experiments, people have favored their own group (arbitrarily created by a simple coin toss) when dividing rewards (Tajfel, 1982; Wilder, 1981). Outside the lab, discrimination is often triggered not by outgroup hostility but by ingroup networking and mutual support, such as hiring a friend’s child at the expense of other candidates (Greenwald & Pettigrew, 2014).

ingroup

“us”—people with whom we share a common identity.

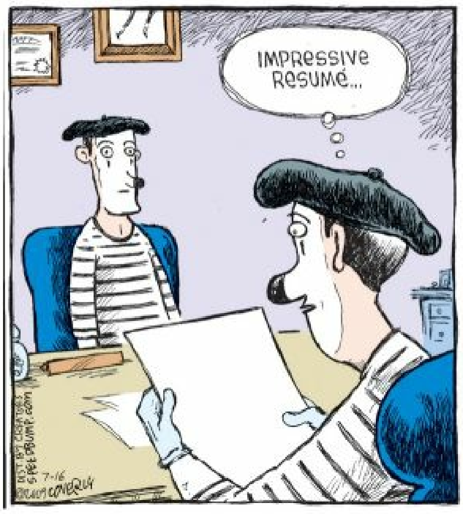
outgroup

“them”—those perceived as different or apart from our ingroup.

ingroup bias

the tendency to favor our own group.

We have inherited our Stone Age ancestors' need to belong, to live and love in groups. There was safety in solidarity: Whether hunting, defending, or attacking, 10 hands were better than 2. Evolution prepared us, when encountering strangers, to make instant judgments: friend or foe? This urge to distinguish enemies from friends, and to "otherize" as different those not like us, predisposes prejudice against strangers (Whitley, 1999). To Greeks of the classical era, all non-Greeks were "barbarians." In our own era, most students believe their school is better than all other schools in town. Perhaps you can recall being most conscious of your school identity when competing with an archrival school. Many high school students form cliques—jocks, preps, nerds—and disparage those outside their own group. Even chimpanzees have been seen to wipe clean the spot where they were touched by a chimpanzee from another group (Goodall, 1986). They also display ingroup empathy by yawning more after seeing ingroup (rather than outgroup) members yawn (Campbell & de Waal, 2011). An ideal world might equally prioritize justice and love for all. But in our real world, ingroup love often outranks universal justice.



IMPRESSIVE RESUMÉ...

Negative Emotions

Negative emotions nourish prejudice. When facing death, fearing threats, or experiencing frustration, people cling more tightly to their ingroup and their friends. As fears of terrorism heighten patriotism, they also produce loathing and aggression toward "them"—those who threaten our world

(Pyszczynski et al., 2002, 2008). **Scapegoat theory** notes that when things go wrong, finding someone to blame can provide a target for our negative emotions. Following the 9/11 attacks, some outraged people lashed out at innocent Arab-Americans. A decade later, anti-Muslim animosities still flare. In 2015, anti-Muslim hate crimes rose 67 percent from the year before (FBI, 2016). And after anti-immigrant sentiments flared in 2016 during the Brexit referendum in Britain and the contentious presidential election in the United States, reports of harassment, bullying, and hate crime rose (Crandall & White, 2016; Hassan, 2016; Kenyon, 2016; North, 2016). “Fear and anger create aggression, and aggression against citizens of different ethnicity or race creates racism and, in turn, new forms of terrorism,” noted Philip Zimbardo (2001).

scapegoat theory

the theory that prejudice offers an outlet for anger by providing someone to blame.

HOPE
HOPE 40

The ingroup Basketball fans, shown here from my [DM’s] own college during a game against their archrival, share a social identity that defines “us” (the ingroup) and “them” (the outgroup).

Evidence for the scapegoat theory of prejudice comes in two forms: (1) Economically frustrated people tend to express heightened prejudice. (2) Experiments that create temporary frustration intensify prejudice. Students who experience failure or are made to feel insecure often restore their self-esteem by belittling a rival school or another person (Cialdini & Richardson, 1980; Crocker et al., 1987). Denigrating others may boost our own sense of status, which explains why a rival's misfortune sometimes provides a twinge of pleasure. (The German language has a word—*Schadenfreude*—for this secret joy that we sometimes take in another's failure.) By contrast, those made to feel loved and supported become more open to and accepting of others who differ (Mikulincer & Shaver, 2001).

Cognitive Shortcuts

Stereotyped beliefs are in part a by-product of how we cognitively simplify the world. To help understand the world around us, we sometimes *form categories.* Chemists categorize molecules as organic and inorganic. A basketball coach categorizes offensive players as guards and post players. Therapists categorize psychological disorders. We all categorize people by gender, ethnicity, race, age, and many other characteristics. But when we categorize people into groups, we often stereotype. We recognize how greatly *we* differ from other individuals in *our* groups. But we overestimate the extent to which members of other groups are alike (Bothwell et al., 1989). We perceive *outgroup homogeneity*—uniformity of outgroup attitudes, personality, and appearance. Our greater recognition for individual own-race faces—called the **other-race effect** (or *cross-race effect* or *own-race bias*)—emerges during infancy, between 3 and 9 months of age (Anzures et al., 2013; Telzer et al., 2013). (We also have an *own-age bias*—better recognition memory for faces of our own age group

[Rhodes & Anastasi, 2012]).

other-race effect

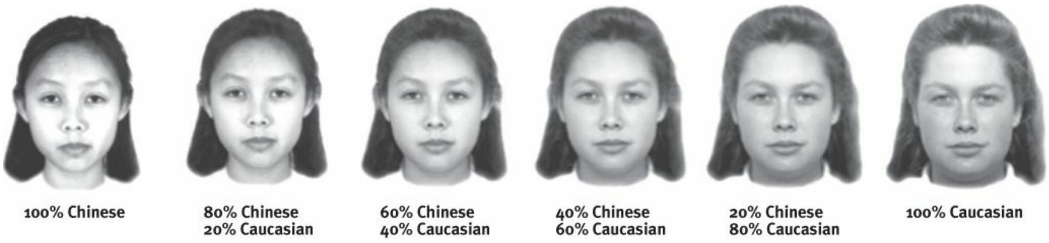
the tendency to recall faces of one’s own race more accurately than faces of other races. Also called the *cross-race effect* and the *own-race bias.*

AP® EXAM TIP

Pause for a minute and try to identify examples of the just-world phenomenon, ingroup bias, and scapegoating in your own school.

> “*The misfortunes of others are the taste of honey.*”
>
> *Japanese saying*

Sometimes, however, people don’t fit easily into our racial categories. For example, mixed-race people are often assigned to their minority identity. Researchers believe this happens because, after learning the features of a familiar racial group, the observer’s selective attention is drawn to the distinctive features of the less-familiar minority. Researchers illustrated this learned-association effect by showing New Zealanders blended Chinese-Caucasian faces (Halberstadt et al., 2011). Compared with participants of Chinese descent, European-descent New Zealanders more readily classified ambiguous faces as Chinese (see **Figure 77.3**). With effort and with experience, people get better at recognizing individual faces from another group (Hugenberg et al., 2010; Young et al., 2012).



100% Chinese
80% Chinese 20% Caucasian
60% Chinese 40% Caucasian
40% Chinese 60% Caucasian
20% Chinese 80% Caucasian
100% Caucasian

Remembering Vivid Cases

As we saw in Module 35, we also simplify our world by employing *heuristics*—mental shortcuts that enable snap judgments. The *availability heuristic* is the tendency to estimate the frequency of an event by how readily it comes to mind. Vivid cases are memorable and they come to mind easily, so it's no surprise that they feed our stereotypes. In a classic experiment, researchers showed two groups of University of Oregon students lists containing information about 50 men (Rothbart et al., 1978). The first group's list included 10 men arrested for *nonviolent* crimes, such as forgery. The second group's list included 10 men arrested for *violent* crimes, such as assault. Later, both groups were asked how many men on their list had committed *any* sort of crime. The second group overestimated the number. Violent crimes form vivid memories (**Figure 77.4**).

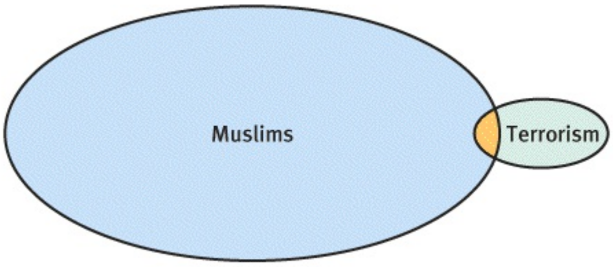

Figure 77.4
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 77.4 Vivid cases feed stereotypes

Global terrorism has created, in many minds, an exaggerated stereotype of Muslims as terrorism-prone. Actually, reported a U.S. National Research Council panel on terrorism, when offering this inexact illustration, most terrorists are not Muslim and "the vast majority of Islamic people have no connection with and do not sympathize with terrorism" (Smelser & Mitchell, 2002).

Victim Blaming

As we noted earlier, people often justify their prejudices by blaming victims. If the world is just, they assume, people must get what they deserve. As one German civilian is said to have remarked when visiting the Bergen-Belsen concentration camp shortly after World War II, "What terrible criminals these prisoners must have been to receive such treatment."

Hindsight bias amplifies victim blaming (Carli & Leonard, 1989). Have you ever heard people say that rape victims, abused spouses, or people with AIDS got what they deserved? In some countries, such as Pakistan, rape victims have been sentenced to severe punishment for violating adultery prohibitions (Mydans, 2002). In one experiment, two groups of people were given a detailed account of a date (Janoff-Bulman et al., 1985). The first group's account reported that the date ended with the woman being raped. Members of that group perceived the woman's behavior as at least partly to blame, and in hindsight, they thought, “She should have known better.” The second group, given the same account with the rape ending deleted, did not perceive the woman’s behavior as inviting rape. Hindsight bias promoted a blame-the-victim mentality among members of the first group. Blaming the victim also serves to reassure people that it couldn’t happen to them.

People also have a basic tendency to justify their culture’s social systems (Jost et al., 2009; Kay et al., 2009). We’re inclined to see the way things are as the way they ought to be and deserve to be. If people are rich, they must be smart (Hussak & Cimpian, 2015). This natural conservatism makes it difficult to legislate major social changes, such as health care or climate change policies. Once such policies are in place, our “system justification” tends to preserve them.

If your own gut-check reveals you sometimes have feelings you would rather not have about other people, remember this: It is what we *do* with our feelings that matters. By monitoring our feelings and actions, and by replacing old habits with new ones based on new friendships, we can work to free ourselves from prejudice.

✓ Check Your Understanding

Ask Yourself

- What are some examples of ingroup bias in your community?

Test Yourself

- What is the difference between prejudice and discrimination?
- When prejudiced judgment causes us to blame an undeserving person for a problem, that person is called a _______________.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 77 REVIEW

77-1 What is *prejudice?* How do explicit and implicit prejudice differ?

- *Prejudice* is an unjustifiable, usually negative attitude toward a group and its members.
- Prejudice's three components are beliefs (often *stereotypes*), emotions, and predispositions to action *(discrimination).*
- Explicit (overt, observable) prejudice in North America has decreased over time, but implicit prejudice—an unthinking knee-jerk response operating below conscious awareness—continues. Psychologists study implicit prejudice by testing for unconscious group associations, considering unconscious patronization, and monitoring reflexive bodily responses.

77-2 What groups are frequent targets of prejudice?

- Prejudice involves both explicit and implicit negative attitudes toward people of a particular racial or ethnic group, gender, sexual orientation, or belief system.

77-3 What are some social, emotional, and cognitive roots of prejudice, and what are some ways to eliminate prejudice?

- The social roots of prejudice include social inequalities and divisions.
    - Higher-status groups often justify their privileged position with the *just-world phenomenon.*
    - We tend to favor our own group *(ingroup bias)* as we divide ourselves into "us" (the *ingroup*) and "them" (the *outgroup*).
- Prejudice can also be a tool for protecting our emotional well-being, as when we focus our anger by blaming events on a *scapegoat.*

- The cognitive roots of prejudice grow from our natural ways of processing information: forming categories, remembering vivid cases, and believing that the world is just (and that our own and our group's ways of doing things are the right ways).
- Monitoring our feelings and actions, as well as developing new friendships, can help us free ourselves from prejudice.

Multiple-Choice Questions

1. The primary distinction between prejudice and discrimination is that

a. prejudice is cognitive and discrimination is a behavior.
b. prejudice is based on anger and discrimination is based on fear.
c. prejudice is a legal term and discrimination is a psychological term.
d. prejudice typically develops in infancy and discrimination typically develops in adolescence.
e. discrimination is primarily caused by nature and prejudice is primarily caused by nurture.

2. In recent years,

a. both explicit and implicit prejudice have shown steady and equal increases.
b. explicit prejudice has decreased, but implicit prejudice has not.
c. both explicit and implicit prejudice have been increasing, but explicit prejudice is increasing at a faster rate.
d. both explicit and implicit prejudice have been increasing, but implicit prejudice is increasing at a faster rate.
e. explicit prejudice has been decreasing more than implicit prejudice.

3. Which of the following accurately describes the just-world phenomenon?

a. It's the reduction in prejudice that has resulted from improvements in our laws and judicial system.
b. It's the reduction in discrimination that has resulted from improvements in our laws and judicial system.

c. It's the belief that most people get what they deserve and deserve what they get.
d. It's the tendency of people to deny that prejudice is still a problem.
e. It's a reflection of our desire to categorize daily events as "unfair."

4. Which of the following is an example of ingroup bias?

a. Hinata talked only to her five best friends when she was in ninth grade.
b. Sabrina has been a New York Yankees fan since she was in fourth grade.
c. Kimia believes she is the best student in her AP® psychology class, but her grades are not as good as several other students.
d. Francisco believes he is the best student in his AP® psychology class, and in fact he has the highest test average.
e. Derek believes his T-ball team is the best in the league and that the other teams in the league have no talented players.

5. What is the best explanation for why Carl, an African-American, was better able to describe the African-American man who robbed his store than he was able to describe the Caucasian man who was with him?

a. Scapegoat theory
b. A vivid case
c. Just-world phenomenon
d. The other-race effect
e. Ingroup bias

Practice FRQs

1. Give an example that is not mentioned in the text for each of the three major components of prejudice.

Answer

1 point: *Stereotyped judgments* are generalized, negative beliefs about a group of people, such as assuming they are all elitist or all lazy. The point is awarded for an example that is not cited in the text. ↩ Page 792

1 point: Prejudice also involves *negative emotions*, such as hostility or fear, toward the members of a group. The point is awarded for an example that is not cited in the text. ↩ Page 792

1 point: A *predisposition to discriminate* against members of a group could be expressed by refusing to date or hire people in that group. The point is awarded for an example that is not cited in the text. ↩ Page 792

2. Describe an example of a social root of prejudice, an emotional root of prejudice, and a cognitive root of prejudice.

(3 points)

Module **78 Aggression**

LEARNING TARGETS

- 78-1 Explain how psychology's definition of *aggression* differs from everyday usage, and identify the biological factors that make us more prone to hurt one another.
- 78-2 Outline the psychological and social-cultural triggers of aggression.

78-1 How does psychology's definition of *aggression* differ from everyday usage? What biological factors make us more prone to hurt one another?

Prejudice hurts, but aggression sometimes hurts more. In psychology, **aggression** is any physical or verbal behavior intended to harm someone, whether done out of hostility or as a calculated means to an end. The assertive, persistent salesperson is not aggressive. Nor is the dentist who makes you wince with pain. But the high school gossip who passes along a vicious rumor about you, the bully who torments you in person or online, and the attacker who mugs you for your money are aggressive.

aggression
any physical or verbal behavior intended to harm someone physically or emotionally.

Aggressive behavior emerges from the interaction of biology and experience. For a gun to fire, the trigger must be pulled; with some people, as with hair-trigger guns, it doesn’t take much to trip an explosion. Let’s look first at some biological factors that influence our thresholds for aggressive behavior, then at the psychological factors that pull the trigger.

The Biology of Aggression

Aggression varies too widely from culture to culture, era to era, and person to person to be considered an unlearned instinct. But biology does *influence* aggression. We can look for biological influences at three levels—genetic, neural, and biochemical.

Gilbert Laurie/Getty Images

Do guns in the home save or take more lives? “Personal safety/protection” is the #1 reason U.S. gun owners give for firearm ownership (Swift, 2013). Yet in the last 40 years, well over one million Americans have suffered nonwar firearm deaths—more than all American war deaths. Compared with people of the same sex, race, age, and neighborhood, those who keep a gun in the home have been twice as likely to be murdered and three times as likely to commit suicide (Anglemyer et al., 2014; Stroebe, 2013). States and countries with high gun ownership rates also tend to have high gun death rates (VPC, 2013).

Genetic Influences

Genes influence aggression. Animals have been bred for aggressiveness—sometimes for sport, sometimes for research. The effect of genes also appears in human twin studies (Miles & Carey, 1997; Rowe et al., 1999). If one identical twin admits to “having a violent temper,” the other twin will often independently admit the same. Fraternal twins are much less likely to respond similarly.

Researchers continue to search for genetic markers in those who commit violent acts. One is already well known and is carried by half the human race: the Y chromosome. Another such marker is the *monoamine oxidase A (MAOA) gene,* which helps break down neurotransmitters such as dopamine and serotonin. Sometimes called the “warrior gene,” people who have low MAOA gene expression tend to behave aggressively when provoked. In one experiment, low (compared with high) MAOA gene carriers gave more unpleasant hot sauce to someone who provoked them (McDermott et al., 2009; Tiihonen et al., 2015).

Donald Reilly The New Yorker Collection/The Cartoon Bank

“It’s a guy thing.”

Neural Influences

There is no one spot in the brain that controls aggression. Aggression is a complex behavior, and it occurs in particular contexts. But animal and human brains have neural systems that, given provocation, will either inhibit or facilitate aggression (Falkner et al., 2016; Moyer, 1983; Wilkowski et al., 2011). Consider:

- Researchers implanted a radio-controlled electrode in the brain of the domineering leader of a caged monkey colony. The electrode was in an area that, when stimulated, inhibits aggression. When researchers placed the control button for the electrode in the colony’s cage, one small monkey learned to push it every time the boss became threatening.
- A neurosurgeon, seeking to diagnose a disorder, implanted an electrode in the amygdala of a mild-mannered woman. Because the brain has no sensory receptors, she was unable to feel the stimulation. But at the flick of a switch she snarled, “Take my blood pressure. Take it now,” then

stood up and began to strike the doctor.

- Studies of violent criminals have revealed diminished activity in the frontal lobes, which play an important role in controlling impulses. If the frontal lobes are damaged, inactive, disconnected, or not yet fully mature, aggression may be more likely (Amen et al., 1996; Davidson, 2000; Raine, 2013).

AP® EXAM TIP

Notice that you’re back to a nature and nurture analysis again. The biology section is, of course, the nature component. When you get to the psychological and social-cultural factors coming up, that’s nurture.

Biochemical Influences

Our genes engineer our individual nervous systems, which operate electrochemically. The hormone testosterone, for example, circulates in the bloodstream and influences the neural systems that control aggression. A raging bull becomes a gentle giant when castration reduces its testosterone level. Conversely, when injected with testosterone, gentle, castrated mice once again become aggressive.

Humans are less sensitive to hormonal changes. But as men’s testosterone levels diminish with age, hormonally charged, aggressive 17-year-olds mature into quieter and gentler 70-year-olds.

Facial width is testosterone-linked. A high facial width-to-height ratio is a predictor of men’s aggressiveness and prejudicial attitudes (Carré et al., 2009; Hehman et al., 2013; Stirrat & Perrett, 2010). Women apparently pick up on this by *perceiving* men with higher facial width-to-height ratios as more dominant (Valentine et al., 2014). Other high-testosterone-linked traits among males include irritability, assertiveness, impulsiveness, hard drug use, and low tolerance for frustration (Dabbs et al., 2001; McAndrew, 2009; Montoya et al., 2012; Olweus et al., 1988). Drugs that sharply reduce testosterone levels subdue men’s aggressive tendencies.

> “*We could avoid two-thirds of all crime simply by putting all able-bodied young men in cryogenic sleep from the age of 12 through 28.*”
>
> *David T. Lykken,* The Antisocial Personalities, *1995*

Another drug that sometimes circulates in the bloodstream—alcohol—*unleashes* aggressive responses to frustration. Across police data, prison surveys, and experiments, aggression-prone adults are more likely to drink, and to become violent when intoxicated (White et al., 1993). Alcohol is a disinhibitor—it slows brain activity that controls judgment and inhibitions. Under its influence, people may interpret ambiguous acts (such as being bumped in a crowd) as provocations and react accordingly (Bègue et al., 2010; Giancola & Corman, 2007). Alcohol has been a factor in 73 percent of homicides in Russia and 57 percent in the United States (Landberg & Norström, 2011).

Chris Courteau/AGE Fotostock

A lean, mean fighting machine—the testosterone-laden female hyena The hyena’s unusual embryology pumps testosterone into female fetuses. The result is revved-up young female hyenas who seem born to fight.

Those who just *think* they’ve imbibed alcohol can become more aggressive (Bègue et al., 2009). But so, too, will those who unknowingly ingest alcohol slipped into a drink. Thus, alcohol affects aggression both biologically and psychologically (Bushman, 1993; Ito et al., 1996; Taylor & Chermack, 1993).

Psychological and Social-Cultural Factors in Aggression

78-2 What psychological and social-cultural factors may trigger aggressive behavior?

Biological factors influence how easily aggression is triggered. But what psychological and social-cultural factors pull the trigger?

Aversive Events

Suffering sometimes builds character. In laboratory experiments, however, those made miserable have often made others miserable (Berkowitz, 1983, 1989). Aversive stimuli—hot temperatures, physical pain, personal insults, foul odors, cigarette smoke, crowding—can evoke hostility. A prime example of this phenomenon is the **frustration-aggression principle**: Frustration creates anger, which can spark aggression. Even hunger can feed anger—making people "hangry" (Bushman et al., 2014).

frustration-aggression principle

the principle that frustration—the blocking of an attempt to achieve some goal—creates anger, which can generate aggression.

The frustration-aggression link was illustrated in an analysis of 27,667 hit-by-pitch Major League Baseball incidents between 1960 and 2004 (Timmerman, 2007). Pitchers were most likely to hit batters when they had been frustrated by one of three events: the previous batter had hit a home run, the current batter had hit a home run the last time at bat, or the pitcher's teammate had been hit by a pitch in the previous half-inning. A separate study found a similar link between rising temperatures and the number of hit batters (Reifman et al., 1991; see **Figure 78.1**). When overheated, we think, feel, and act more aggressively.

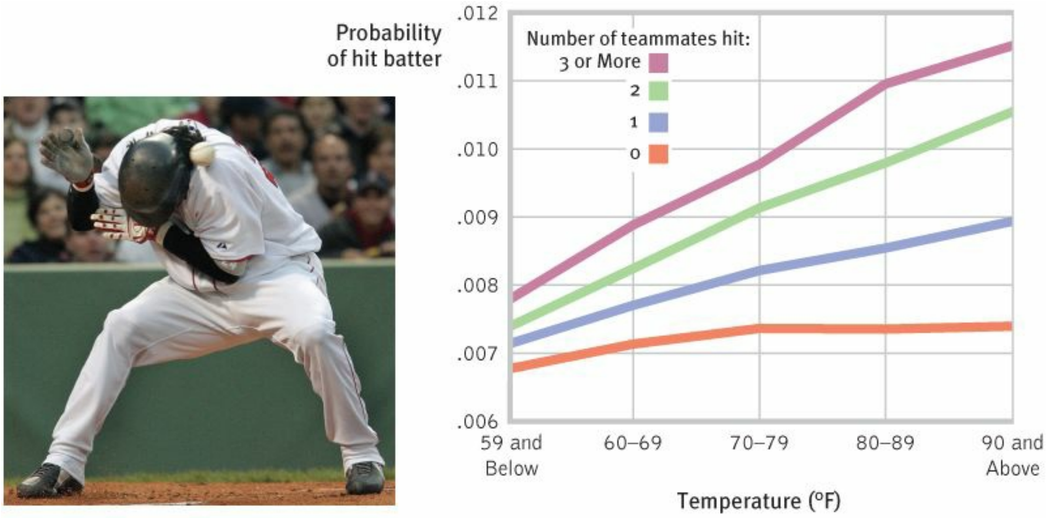

Figure 78.1
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Photo: Brita Meng Outzen/AP Photo

Figure 78.1 Temperature and retaliation

Researchers looked for occurrences of batters hit by pitchers during 4,566,468 pitcher-batter matchups across 57,293 Major League Baseball games since 1952 (Larrick et al., 2011). The probability of a hit batter increased if one or more of the pitcher's teammates had been hit, and also with temperature.

In the wider world, violent crime and spousal abuse rates have been higher during hotter years, seasons, months, and days (Anderson et al., 1997). Studies from archaeology, economics, geography, political science, and psychology converge in finding that throughout human history, higher temperatures have predicted increased individual violence, wars, and revolutions (Hsiang et al., 2013). Craig Anderson and his colleagues (2000, 2011) have projected that, other things being equal, global warming of 4 degrees Fahrenheit (about 2 degrees Celsius) could induce tens of thousands of additional assaults and murders—and that's before the added violence inducements from climate change–related drought, poverty, food insecurity, and migration.

Reinforcement, Modeling, and Self-Control

Aggression may naturally follow aversive events, but learning can alter natural reactions. As Unit VI explained, we learn when our behavior is reinforced, and we learn by watching others.

AP® EXAM TIP

This is a good opportunity to review Unit VI yet again. You should go back for a quick review if you don’t recognize the basic components of operant conditioning and observational learning in this material.

In situations where experience has taught us that aggression pays, we are likely to act aggressively again. Children whose aggression has successfully intimidated other children may become bullies. Animals that have successfully fought to get food or mates become increasingly ferocious. To foster a kinder, gentler world we had best model and reward sensitivity and cooperation from an early age, perhaps by training parents to discipline without modeling violence.

Parent-training programs often advise parents to avoid modeling violence by screaming and hitting. Instead, parents should reinforce desirable behaviors and frame statements positively. (“When you finish loading the dishwasher you can go play,” rather than “If you don’t load the dishwasher, there’ll be no playing.”)

Different cultures model, reinforce, and evoke different tendencies toward violence. For example, crime rates have also been higher and average happiness lower in times and places marked by a great disparity between rich and poor (Messias et al., 2011; Oishi et al., 2011; Wilkinson & Pickett, 2009). In the United States, cultures and families in which fathers are minimally involved have had high violence rates (Triandis, 1994). Even after controlling for parental education, race, income, and teen motherhood, American male youths from father-absent homes are incarcerated at twice the rate of their peers (Harper & McLanahan, 2004).

Violence can vary by culture within a country. Researchers analyzed violence among White Americans in southern towns settled by Scots-Irish herders whose tradition emphasized “manly honor,” the use of arms to protect one’s flock, and a history of coercive slavery (Nisbett & Cohen, 1996). Compared with their White counterparts in New England towns settled by the more traditionally peaceful Puritan, Quaker, and Dutch farmer-artisans, the cultural descendants of those herders had triple the homicide rates and were more supportive of physically punishing children, of warfare initiatives, and of uncontrolled gun ownership. “Culture-of-honor” states also had higher rates of students bringing weapons to school and of school shootings (Brown et al., 2009).

Media Models for Violence

Parents are hardly the only aggression models. In the United States and elsewhere, TV, films, video games, and the Internet offer supersized portions of violence. An adolescent boy faced with a real-life challenge may “act like a man”—at least like an action-film man—by intimidating or eliminating the threat. As we learned in Module 30, violent video game playing tends to make us less sensitive to cruelty (Arriaga et al., 2015). It also primes us to respond aggressively when provoked. And media violence teaches us **social scripts**—culturally provided mental files for how to act in certain situations. As more than 100 studies confirm, we sometimes imitate what we’ve viewed. Watching risk-glorifying behaviors (dangerous driving, extreme sports, unprotected sex) increases real-life risk-taking (Fischer et al., 2011).

social script

a culturally modeled guide for how to act in various situations.

Music lyrics also write social scripts. German university men who listened to woman-hating lyrics administered the most hot chili sauce to a woman. They also recalled more negative feelings and beliefs about women. Listening to man-hating lyrics had a similar effect on women (Fischer & Greitemeyer, 2006).

How does repeatedly watching pornographic films affect viewers? As pornography has become more easily available, rates of reported sexual violence have decreased in the United States (though not in Canada, Australia, and Europe). Nevertheless, just as repeated viewing of onscreen violence helps immunize us to aggression, repeated viewing of pornography—even nonviolent pornography—makes sexual aggression seem less serious (Harris, 1994). In one experiment, undergraduates viewed six brief films each week for six weeks (Zillmann & Bryant, 1984). Some viewed sexually explicit films; others viewed films with no sexual content. Three weeks later, both groups, after reading a report about a man convicted of raping a female hitchhiker, suggested an appropriate prison term. Compared with sentences recommended by the control group, the sex film viewers recommended terms that were half as long. In other studies that explored pornography's effects on aggression toward relationship partners, pornography consumption predicted both self-reported aggression and participants' willingness to administer laboratory noise blasts to their partner (Lambert et al., 2011; Peter & Valkenburg, 2016).

AP® EXAM TIP

In the hitchhiker experiment described here, can you identify the independent and dependent variables? It's great practice to do this every time you read about an experiment.

Pornography with violent sexual content can increase men's readiness to behave aggressively toward women. A statement by 21 social scientists noted, "Pornography that portrays sexual aggression as pleasurable for the victim increases the acceptance of the use of coercion in sexual relations" (Surgeon General, 1986). Contrary to much popular opinion, viewing such scenes does not provide an outlet for bottled-up impulses. Rather, "in laboratory studies measuring short-term effects, exposure to violent pornography increases punitive behavior toward women."

Do Violent Video Games Teach Social Scripts for Violence?

Experiments worldwide indicate that playing positive games produces positive effects (Greitemeyer & Mügge, 2014; Prot et al., 2014). For example, playing *Lemmings*, where a goal is to help others, increases real-life helping. So, might a parallel effect occur after playing games that enact violence? Violent video games became an issue for public debate after teenagers in more than a dozen places seemed to mimic the carnage in the shooter games they had so often played (Anderson, C. A., 2004, 2013).

In 2002, three young men in Michigan spent part of a night drinking beer and playing *Grand Theft Auto III.* Using simulated cars, they ran down pedestrians, then beat them with fists, leaving a bloody body behind (Kolker, 2002). These same young men then went out for a real drive. Spotting a 38-year-old man on a bicycle, they ran him down with their car, got out, stomped and punched him, and returned home to play the game some more. (The victim, a father of three, died six days later.)

AFP/Getty Images

Coincidence or cause? In 2011, Norwegian Anders Behring Breivik bombed government buildings in Oslo, and then went to a youth camp where he shot and killed 69 people, mostly teens. As a player of first-person shooter games, Breivik stirred debate when he commented that “I see MW2 *[Modern Warfare 2]* more as a part of my training-simulation than anything else.” Did his violent game playing—and that of the 2012 mass murderer of Newtown, Connecticut’s first-grade children—contribute to the violence, or was it a merely coincidental association? To explore such questions, psychologists experiment.

This is but one anecdote, and, as we say in psychological science, “the plural of anecdote is not evidence.” Yet such incidents of violent mimicry make us wonder: What *are* the effects of actively role-playing aggression? Does it cause young people to become less sensitive to violence and more open to violent acts? Nearly 400 studies of 130,000 people offer some answers (Anderson et al., 2010; Calvert et al., 2017): Video games can prime aggressive thoughts, decrease empathy, and increase aggression. University men who spend the most hours playing violent video games have also tended to be the most physically aggressive (Anderson & Dill, 2000). (For example, they more often acknowledged having hit or attacked someone else.) And people randomly assigned to play a game involving bloody murders with groaning victims (rather than to play nonviolent *Myst*) became more hostile. On a follow-up task, they were more likely to blast intense noise at a fellow student. Studies of young adolescents reveal that those who play a lot of violent video games become more aggressive and see the world as more hostile (Bushman, 2016; Exelmans et al., 2015; Gentile, 2009). Compared with nongaming kids, they get into more arguments and fights and earn poorer grades.

Ah, but is this merely because naturally hostile kids are drawn to such games? Apparently not. Comparisons of gamers and nongamers who scored low on hostility measures revealed a difference in the number of fights they reported. Almost 4 in 10 violent-game players had been in fights, compared with only 4 in 100 of the nongaming kids (Anderson, C. A., 2004). Some researchers believe that, due partly to the more active participation and rewarded violence of game play, violent video games have even greater effects on aggressive behavior and cognition than do violent TV shows and movies (Anderson & Warburton, 2012).

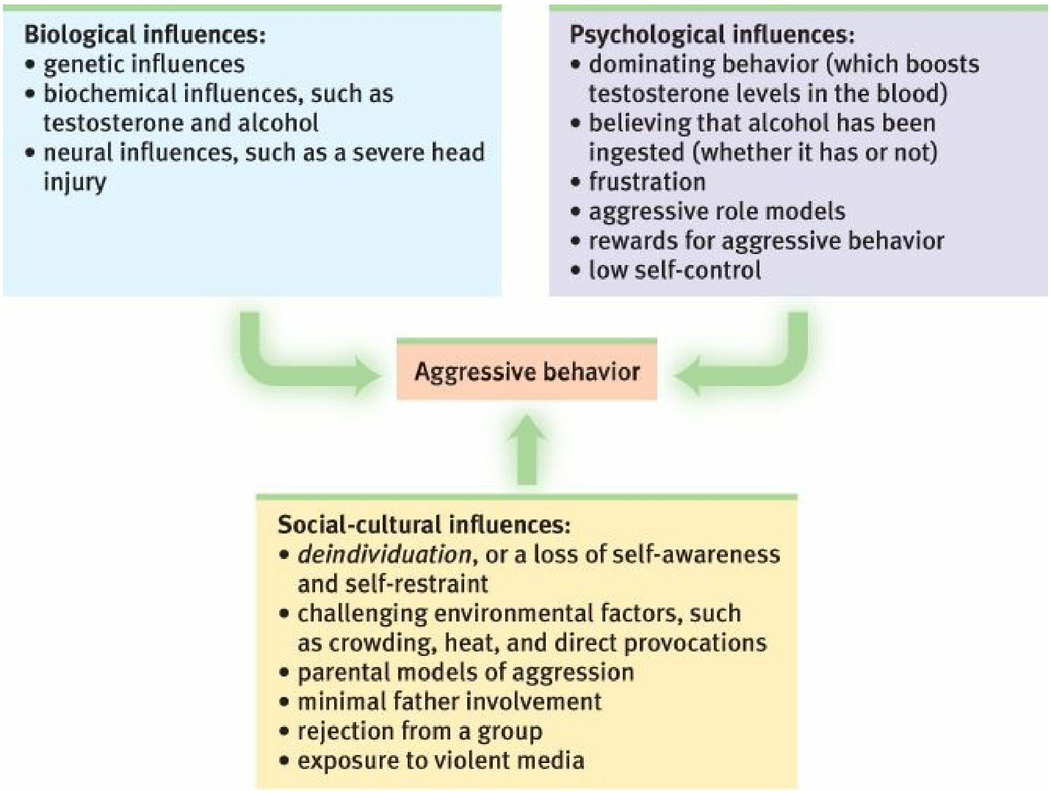
> “ *Research demonstrates a consistent relation between violent video game use and increases in aggressive behavior, aggressive cognitions and aggressive affect, and*

> *decreases in prosocial behavior, empathy and sensitivity to aggression.*”
>
> *American Psychological Association Task Force on Violent Media, 2015*

Other researchers are unimpressed by such findings (Ferguson, 2013, 2014, 2015). They note that from 1996 to 2006, video game sales increased yet youth violence declined. They argue that other factors—depression, family violence, peer influence—better predict aggression. The focused fun of game playing can also satisfy basic needs for a sense of competence, control, and social connection (Granic et al., 2014).

* * *

To sum up, research reveals biological, psychological, and social-cultural influences on aggressive behavior. Complex behaviors, including violence, have many causes, making any single explanation an oversimplification. Asking what causes violence is therefore like asking what causes cancer. Those who study the effects of asbestos exposure on cancer rates may remind us that asbestos is indeed a cancer cause, but it is only one among many. Like so much else, aggression is a biopsychosocial phenomenon (**Figure 78.2**).



Biological influences:
• genetic influences
• biochemical influences, such as testosterone and alcohol
• neural influences, such as a severe head injury
Psychological influences:
• dominating behavior (which boosts testosterone levels in the blood)
• believing that alcohol has been ingested (whether it has or not)
• frustration
• aggressive role models
• rewards for aggressive behavior
• low self-control
Aggressive behavior
Social-cultural influences:
• *deindividuation*, or a loss of self-awareness and self-restraint
• challenging environmental factors, such as crowding, heat, and direct provocations
• parental models of aggression
• minimal father involvement
• rejection from a group
• exposure to violent media

Figure 78.2

Figure 78.2 Biopsychosocial understanding of aggression

Because many factors contribute to aggressive behavior, there are many ways to change such behavior, including learning anger management and communication skills, and avoiding violent media and video games.

A happy concluding note: Historical trends suggest that the world is becoming less violent over time (Pinker, 2011). That people vary across time and place reminds us that environments differ. Yesterday's plundering Vikings have become today's peace-promoting Scandinavians. Like all behavior, aggression arises from the interaction of persons and situations.

✓ Check Your Understanding

Ask Yourself

- Do you think there should be laws to prevent children's exposure to violent media? Why or why not?

Test Yourself

- What psychological, biological, and social-cultural influences interact to produce aggressive behaviors?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 78 REVIEW

78-1 How does psychology's definition of *aggression* differ from everyday usage? What biological factors make us more prone to hurt one another?

- In psychology's more specific meaning, *aggression* is any act intended to harm someone physically or emotionally.
- Biology influences our threshold for aggressive behaviors at three levels: genetic (inherited traits), neural (activity in key brain areas), and biochemical (such as alcohol or excess testosterone in the bloodstream).
- Aggression is a complex behavior resulting from the interaction of biology and experience.

78-2 What psychological and social-cultural factors may trigger aggressive behavior?

- Frustration (*the frustration-aggression principle*), previous reinforcement for aggressive behavior, observing an aggressive role model, and poor self-control can all contribute to aggression.
- Media portrayals of violence provide *social scripts* that children learn to follow.
- Viewing sexual violence contributes to greater aggression toward women.
- Playing violent video games increases aggressive thoughts, emotions, and behaviors.

Multiple-Choice Questions

1. Brandt's football team just barely lost the state championship game after a questionable referee call. As a result, Brandt gets angry and starts shouting insults. Which of the following terms best identifies this chain of events?

   a. Aggression
   b. Biochemical influences
   c. Frustration-aggression principle
   d. Social scripts
   e. Biopsychosocial model

2. Dwayne is acting violently toward his friends and family. A PET scan of his brain may show

   a. increased frontal lobe activity.
   b. diminished activity in the amygdala.
   c. decreased frontal lobe activity.
   d. a decrease in the size of the hippocampus.
   e. enlarged ventricles.

3. Which of the following is an example of a social-cultural influence on aggressive behavior?

   a. Reading an anxiety-provoking novel
   b. Frustration
   c. Testosterone
   d. Exposure to violent media
   e. Genetics

Practice FRQs

1. Using the biopsychosocial model, name a biological influence, a social-cultural influence, and a psychological influence on aggressive behavior.

Answer

1 point: Possible biological influences: genetic, biochemical (for example, testosterone), or neural (for example, severe frontal lobe injury). Page 801

1 point: Possible social-cultural influences: deindividuation, provocation, minimal father involvement, exposure to violent media, rejection from a group, or parental models of aggression. Page 803

1 point: Possible psychological influences: dominating behavior, believing one has consumed alcohol, low self-control, frustration, aggressive role models, or rewards for aggressive behavior. Page 803

2. Explain how social scripts and the frustration-aggression principle can be linked to an increase in violence after viewing violence.

(2 points)

Module **79 Attraction**

LEARNING TARGETS

- **79-1 Explain why we befriend or fall in love with some people but not others.**
- **79-2 Describe how romantic love typically changes as time passes.**

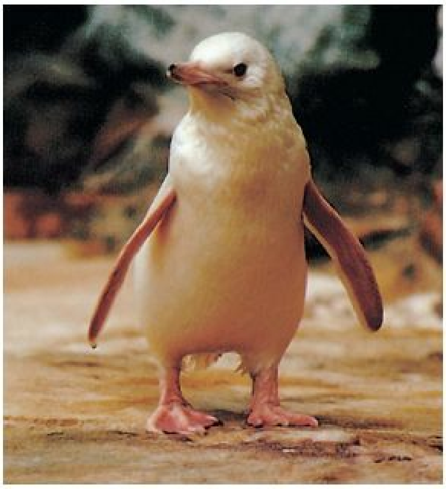
As social animals—as people who need people—we often approach people not with closed fists, but with open arms. Social psychologists focus not only on the dark side of social relationships, but also on the bright side, by studying *prosocial* behavior—behavior that intends to help or benefit someone. Our positive behaviors toward others are evident from explorations of this module’s focus, attraction, and those of the next module, altruism and peacemaking.

Pause a moment and think about your relationships with two people—a close friend, and someone who has stirred your romantic feelings. What psychological chemistry binds us together in friendship or love? Social psychology suggests some answers.

The Psychology of Attraction

79-1 Why do we befriend or fall in love with some people but not others?

We endlessly wonder how we can win others' affection and what makes our own affections flourish or fade. Does familiarity breed contempt, or does it amplify affection? Do birds of a feather flock together, or do opposites attract? Is it what's inside that counts, or does physical attractiveness matter too? To explore these questions, let's consider three ingredients of our liking for one another: proximity, attractiveness, and similarity.



Brendan Beirne/REX/Shutterstock

Familiarity breeds acceptance When this rare white penguin was born in the Sydney, Australia zoo, his tuxedoed peers ostracized him. Zookeepers thought they would need to dye him black to gain acceptance. But after three weeks of contact, the other penguins came to accept him.

Proximity

Before friendships become close, they must begin. *Proximity*—geographic nearness—is friendship's most powerful predictor. Proximity can provide opportunities for aggression. But much more often it breeds liking (and sometimes even marriage) among those who live in the same neighborhood, sit nearby in class, work in the same office, share the same parking lot, or eat in the same cafeteria. Look around. Matching starts with meeting.

Proximity breeds liking partly because of the **mere exposure effect**. Repeated exposure to novel stimuli increases our liking for them. By age 3 months, infants prefer photos of the race they most often see—usually their own race (Kelly et al., 2007). For our ancestors, this mere exposure effect likely had survival value. What was familiar was generally safe and approachable. What was unfamiliar was more often dangerous and threatening. Evolution may therefore have hard-wired into us the tendency to bond with those who are familiar and to be wary of those whose looks are unfamiliar (Sofer et al., 2015; Zajonc, 1998).

mere exposure effect

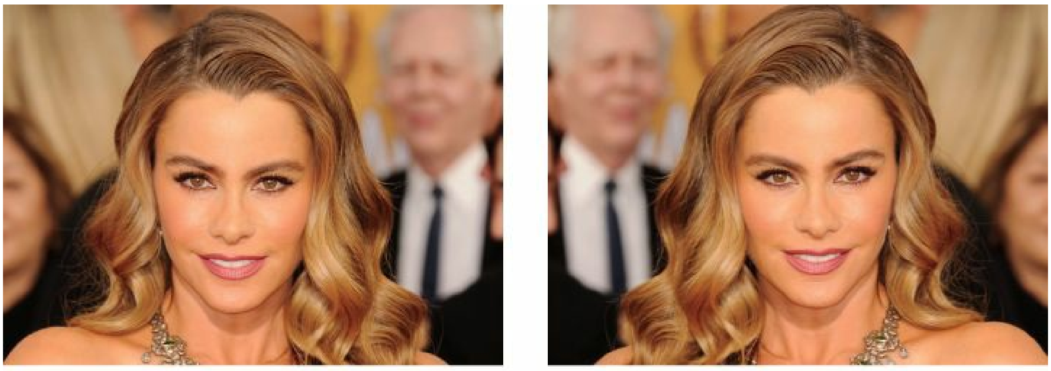
the phenomenon that repeated exposure to novel stimuli increases liking of them.

Mere exposure increases our liking not only for familiar faces, but also for nonsense syllables, musical selections, geometric figures, Chinese characters, and the letters of our own name (Moreland & Zajonc, 1982; Nuttin, 1987; Zajonc, 2001). So, within certain limits, familiarity feeds fondness (Bornstein, 1989, 1999). This would come as no surprise to the young Taiwanese man who wrote more than 700 letters to his girlfriend, urging her to marry him. She did marry—the mail carrier (Steinberg, 1993).

AP® EXAM TIP

Can you remember the other use of the term *proximity* earlier in the course? It's one of the Gestalt principles from Unit IV.

No face is more familiar than your own. And that helps explain an interesting finding by Lisa DeBruine (2002, 2004): We like other people when their faces incorporate some morphed features of our own. When McMaster University students played a game with a supposed other player, they were more trusting and cooperative when the other person's image had some of their own facial features morphed into it. In me I trust.



Jeffrey Mayer/Getty Images

Which is the real Sofía Vergara? The mere exposure effect applies even to ourselves. Because the human face is not perfectly symmetrical, the face we see in the mirror is not the same face our friends see. Most of us prefer the familiar mirror image, while our friends like the reverse (Mita et al., 1977). The person actress Sofía Vergara sees in the mirror each morning is shown at right, and that's the photo she would probably prefer.

Modern Matchmaking

Adults who have not found a romantic partner in their immediate proximity may cast a wider net by joining an online dating service.

Millions search for love on one of the 8000 online dating services (Hatfield, 2016). In 2015, 27 percent of 18- to 24-year-old Americans tried an online dating service or mobile dating app (Smith, 2016).

Online matchmaking definitely expands the pool of potential mates (Finkel et al., 2012a,b). But how effective is the matchmaking? Compared with those formed in person, Internet-formed friendships and romantic relationships are, on average, slightly more likely to last and be satisfying (Bargh & McKenna, 2004; Cacioppo et al., 2013). In one study, people disclosed more, with less posturing, to those whom they met online (McKenna et al., 2002). When conversing online with someone for 20 minutes, they felt more liking for that person than they did for someone they had met and talked with face-to-face. This was true even when (unknown to them) it was the same person! Internet friendships often feel as real and important as in-person relationships.

Small wonder that one survey found a leading online matchmaker enabling more than 500 U.S. marriages a day (Harris Interactive, 2010). By one estimate, online dating now is responsible for about a fifth of U.S. marriages (Crosier et al., 2012). And in a national survey of straight and gay/lesbian couples, nearly a quarter of heterosexual couples and some two-thirds of same-sex couples met online (Rosenfeld & Thomas, 2012; see **Figure 79.1**).

Figure 79.1 Percentage of heterosexual and same-sex couples

who met online

Speed dating pushes the search for romance into high gear. In a process pioneered by a matchmaking Jewish rabbi, people meet a succession of prospective partners, either in person or via webcam (Bower, 2009). After a 3- to 8-minute conversation, people move on to the next prospect. (In an in-person heterosexual meeting, one group—usually the women—remains seated while the other group circulates.) Those who want to meet again can arrange for future contact. For many participants, 4 minutes is enough time to form a feeling about a conversational partner and to register whether the partner likes them (Eastwick & Finkel, 2008a,b).

For researchers, speed dating offers a unique opportunity for studying influences on our first impressions of potential romantic partners. Some recent findings:

- *People who fear rejection often elicit rejection.* After a 3-minute speed date, those who most feared rejection were least often selected for a follow-up date (McClure & Lydon, 2014).
- *Given more options, people make more superficial choices.* When people meet lots of potential partners, they focus on more easily assessed characteristics, such as height and weight (Lenton & Francesconi, 2010).
- *Men wish for future contact with more of their speed dates; women tend to be choosier.* But this difference disappears if the conventional roles are reversed, so that men stay seated while women circulate (Finkel & Eastwick, 2009).

Physical Attractiveness

Once proximity affords us contact, what most affects our first impressions? The person’s sincerity? Intelligence? Personality? Hundreds of experiments reveal that it is something more superficial: physical appearance. This finding is unnerving for those of us taught that “beauty is only skin deep” and “appearances can be deceiving.”

FYI

Percentage of Men and Women Who "Constantly Think About Their Looks"

	Men	Women
Canada	18%	20%
United States	17	27
Mexico	40	45
Venezuela	47	65

From Roper Starch survey, reported by McCool (1999).

In one early study, researchers randomly matched new University of Minnesota students for a Welcome Week dance (Walster et al., 1966). Before the dance, the researchers gave each student a battery of personality and aptitude tests, and they rated each student's physical attractiveness. During the blind date, the couples danced and talked for more than two hours and then took a brief intermission to rate their dates. What predicted whether they liked each other? Only one thing: appearance. Both the men and the women liked good-looking dates best. Women are more likely than men to say that another's looks don't affect them (Lippa, 2007). But studies show that a man's looks do affect women's behavior (Eastwick et al., 2014a,b). In speed-dating experiments, attractiveness influences first impressions for both sexes (Belot & Francesconi, 2006; Finkel & Eastwick, 2008).

Physical attractiveness also predicts how often people date and how popular they feel. And it affects initial impressions of people's personalities. We don't assume that attractive people are more compassionate, but we do perceive them as healthier, happier, more sensitive, more successful, and more socially skilled (Eagly et al., 1991; Feingold, 1992; Hatfield & Sprecher, 1986).

FYI

Estimated length of human nose removed by U.S. plastic surgeons each year: 5469 feet (Harper's, 2009).

For those of us who find the importance of looks unfair and unenlightened, three other findings may be reassuring.

- People's attractiveness is surprisingly unrelated to their self-esteem and happiness (Diener et al., 1995; Major et al., 1984). Unless we have just compared ourselves with superattractive people, few of us (thanks, perhaps, to the mere exposure effect) view ourselves as unattractive (Thornton & Moore, 1993).
- Strikingly attractive people are sometimes suspicious that praise for their work may simply be a reaction to their looks. Less attractive people have been more likely to accept praise as sincere (Berscheid, 1981).
- For couples who were friends before lovers—who became romantically involved long after first meeting—looks matter less (Hunt et al., 2015). With slow-cooked love, shared values and interests matter more.

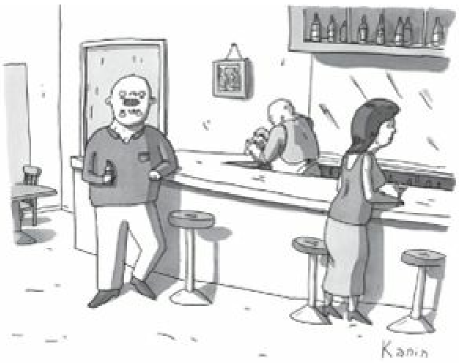
FYI

Women have 91 percent of cosmetic procedures (ASPS, 2010). Women also recall others' appearance better than do men (Mast & Hall, 2006).

Beauty is also in the eye of the culture. Hoping to look attractive, people across the globe have pierced and tattooed their bodies, lengthened their necks, bound their feet, and artificially lightened or darkened their skin and hair. They have gorged themselves to achieve a full figure or liposuctioned fat to achieve a slim one, applied chemicals to rid themselves of unwanted hair or to regrow wanted hair, strapped on leather garments to make their breasts seem smaller or relied on push-up bras and surgery to make them look bigger. Cultural ideals change over time. For women in North America, the ultra-thin ideal of the Roaring Twenties gave way to the soft, voluptuous Marilyn Monroe ideal of the 1950s, only to be replaced by today's lean yet busty ideal.

Left: Sean Caffrey/Getty Images; Center: Blend Images/Alamy; Right: svetikd/Getty Images

In the eye of the beholder Conceptions of attractiveness vary by culture and over time. Yet some adult physical features, such as a healthy appearance and a relatively symmetrical face, seem attractive everywhere.



Zachary Kanin The New Yorker Collection
/The Cartoon Bank

“Play coy if you like, but no one can resist a perfectly symmetrical face.”

Some aspects of heterosexual attractiveness, however, do cross place and time (Cunningham et al., 2005; Langlois et al., 2000). By providing reproductive clues, bodies influence sexual attraction. As evolutionary psychologists explain (Module 15), men in many cultures, from Australia to Zambia, judge women as more attractive if they have a youthful, fertile appearance, suggested by a low waist-to-hip ratio (Karremans et al., 2010; Perilloux et al., 2010; Platek & Singh, 2010). Women feel attracted to healthy-looking men, but especially—and more so when ovulating—to those who seem mature, dominant, masculine, and affluent (Gallup & Frederick, 2010; Gangestad et al., 2010).

Faces matter, too. When people rate opposite-sex faces and bodies separately, the face tends to be the better predictor of overall physical attractiveness (Currie & Little, 2009; Peters et al., 2007). So what makes a face attractive? Part of the answer is features that are neither unusually large nor small. Symmetrical faces and bodies are also perceived as more sexually attractive (Rhodes et al., 1999; Singh, 1995; Thornhill & Gangestad, 1994). This helps explain why an averaged (and therefore symmetrical) face is attractive (**Figure 79.2**). In one clever demonstration, researchers digitized the faces of up to 32 college students and used a computer to average them (Langlois & Roggman, 1990). The result? Viewers judged the averaged, composite faces as more attractive than 96 percent of the individual faces. (If only we could merge either half of our face with its mirror image: Our symmetrical new face would be a notch more attractive.)

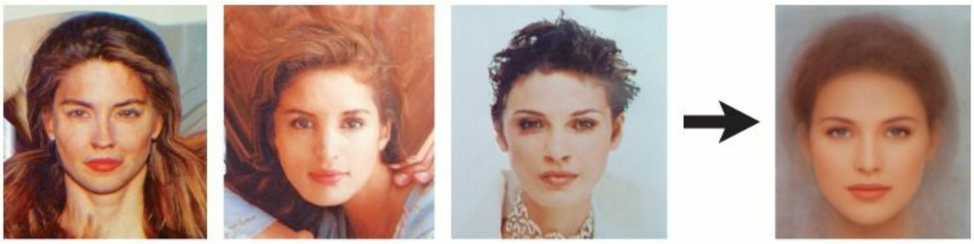


Figure 79.2
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
David Perrett/University of St. Andrews

Figure 79.2 Average is attractive

Which of these faces offered by University of St. Andrews psychologist David Perrett (2002, 2010) is most attractive? Most people say it's the face on the right—of a nonexistent person that is the average composite of these 3 plus 57 other actual faces.

Our feelings also influence our attractiveness judgments. Imagine two people: One is honest, humorous, and polite. The other is rude, unfair, and abusive. Which one is more attractive? Most people perceive the person with the appealing traits as more physically attractive (Lewandowski et al., 2007). Or imagine being paired with a stranger of the sex you find attractive—someone who listens intently to your self-disclosures. Might you feel a twinge of sexual attraction toward that empathic person? Student volunteers did, in several experiments (Birnbaum & Reis, 2012). Our feelings influence our perceptions. Those we like we find attractive.

In a Rodgers and Hammerstein musical, Prince Charming asks

Cinderella, “Do I love you because you’re beautiful, or are you beautiful because I love you?” Chances are it’s both. As we see our loved ones again and again, their physical imperfections grow less noticeable and their attractiveness grows more apparent (Beaman & Klentz, 1983; Gross & Crofton, 1977). Shakespeare said it in *A Midsummer Night’s Dream*: “Love looks not with the eyes, but with the mind.” Come to love someone and watch beauty grow. Love sees loveliness.

Similarity

So proximity has brought you into contact with someone, and your appearance has made an acceptable first impression. What influences whether you will become friends? As you get to know each other, will the chemistry be better if you are opposites or if you are alike?

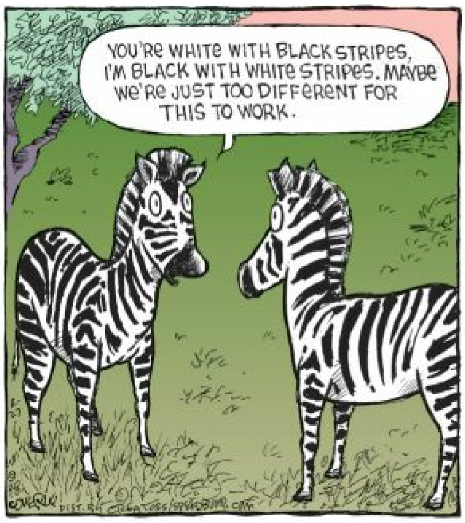
Left: John Shearer/Getty Images; Right: Bennett Raglin/Getty Images

Extreme makeover In affluent, beauty-conscious cultures, increasing numbers of people, such as reality TV star Kylie Jenner, have turned to cosmetic procedures to change their looks.

It makes a good story—extremely different types liking or loving each other: Rat, Mole, and Badger in *The Wind in the Willows*, Frog and Toad in Arnold Lobel’s books, Edward and Bella in the *Twilight* series. The stories delight us by expressing what we seldom experience. In real life, opposites retract (Rosenbaum, 1986; Montoya & Horton, 2013). Compared with randomly paired people, friends and couples are far more likely to share common attitudes, beliefs, and interests (and, for that matter, age, religion, race, education, intelligence, smoking behavior, and economic status). Moreover, the more alike people are, the more their liking endures (Byrne, 1971; Hartl et al., 2015). Journalist Walter

Lippmann was right to suppose that love lasts “when the lovers love many things together, and not merely each other.” Similarity breeds content.

> “*I like the Pope unless the Pope doesn’t like me. Then I don’t like the Pope.*”
>
> *Donald Trump, February 18, 2016*



YOU'RE WHITE WITH BLACK STRIPES, I'M BLACK WITH WHITE STRIPES. MAYBE WE'RE JUST TOO DIFFERENT FOR THIS TO WORK.

© Dave Coverly/speedbump.com

Similarity attracts; perceived dissimilarity does not.

Proximity, attractiveness, and similarity are not the only determinants of attraction. We also like those who like us. This is especially true when our self-image is low. When we believe someone likes us, we feel good and respond to them warmly, which leads them to like us even more (Curtis & Miller, 1986). To be liked is powerfully rewarding.

Indeed, all the findings we have considered so far can be explained by a simple *reward theory of attraction:* We will like those whose behavior is rewarding to us, including those who are both able and willing to help us achieve our goals (Montoya & Horton, 2014). When people live or work in close proximity to us, it requires less time and effort to develop the friendship and enjoy its benefits. When people are attractive, they are aesthetically pleasing, and associating with them can be socially rewarding. When people share our views, they reward us by validating our beliefs.

Check Your Understanding

Ask Yourself

- Think of your closest friends. What factors led to your getting to know them, and to liking them more and more?

Test Yourself

- People tend to marry someone who lives or works nearby. This is an example of the ________________ ________________ ________________ in action.
- How does being physically attractive influence others' perceptions?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Romantic Love

79-2 How does romantic love typically change as time passes?

Sometimes people move quickly from initial impressions, to friendship, to the more intense, complex, and mysterious state of romantic love. If love endures, temporary *passionate love* will mellow into a lingering *companionate love* (Hatfield, 1988).

Passionate Love

Passionate love mixes something new with something positive (Aron et al., 2000; Coulter & Malouff, 2013). We intensely desire to be with our partner (Hatfield et al., 2015). Seeing our partner stimulates blood flow to a brain region linked to craving and obsession (Acevedo et al., 2012).

passionate love

an aroused state of intense positive absorption in another, usually present at the beginning of a romantic relationship.

The two-factor theory of emotion (Module 41) explains the intense positive absorption of romantic love (Hatfield, 1988). That theory assumes that

- emotions have two ingredients—*physical arousal* plus *cognitive appraisal.*
- arousal from any source can enhance one emotion or another, depending on how we interpret and label the arousal.

In tests of the two-factor theory, college men have been aroused by fright, by running in place, by viewing erotic materials, or by listening to humorous or repulsive monologues. They were then introduced to an attractive woman and asked to rate her (or their girlfriend). Unlike unaroused men, the stirred-up men attributed some of their arousal to the woman or girlfriend, and felt more attracted to her (Carducci et al., 1978; Dermer & Pyszczynski, 1978; White & Kight, 1984). In one classic experiment, researchers studied people crossing two bridges above British Columbia's rocky Capilano River (Dutton & Aron, 1974, 1989). One, a swaying footbridge, was 230 feet above the rocks; the other was low and solid. As men came off each bridge, an attractive young woman (working for the researchers) intercepted them and asked them to fill out a short questionnaire. She then offered her phone number in case they wanted to hear more about her project. Far more of the men who had just crossed the high bridge—which left their hearts pounding—accepted the number and later called the woman.

To be revved up and to associate some of that arousal with a desirable person is to feel the pull of passion. Adrenaline makes the heart grow fonder. Sexual desire + a growing attachment = passionate love (Berscheid, 2010).

Companionate Love

Although the desire and attachment of romantic love often endure, the intense absorption in the other, the thrill of the romance, the giddy "floating on a cloud" feelings typically fade. Does this mean the French are correct in saying that "love makes the time pass and time makes love pass"? Or can friendship and commitment keep a relationship going after the passion cools?

As love matures, it typically becomes a steadier **companionate love**—a deep, affectionate attachment (Hatfield, 1988). Like a passing storm, the flood of passion-facilitating hormones (testosterone, dopamine, adrenaline) subsides. But another hormone, *oxytocin,* remains, supporting feelings of trust, calmness, and bonding with the mate. This shift from passion to attachment may have adaptive value (Reis & Aron, 2008). Passionate love often produces children, whose survival is aided by the parents' waning obsession with each other.

companionate love

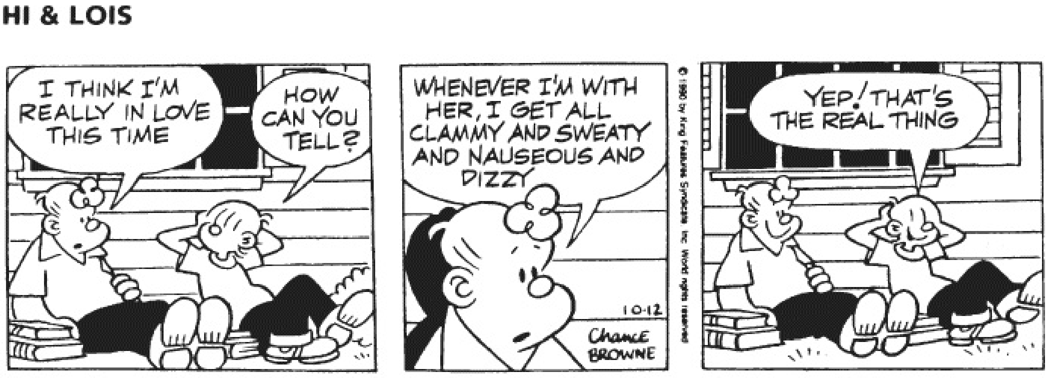
the deep affectionate attachment we feel for those with whom our lives are intertwined.

In the most satisfying marriages, attraction and sexual desire endure, minus the obsession of early stage romance (Acevedo & Aron, 2009). Indeed, failure to appreciate passionate love's limited half-life can doom a relationship (Berscheid et al., 1984). Recognizing the short duration of obsessive passionate love, some societies deem such feelings an irrational reason for marrying. Better, they say, to search for (or have someone choose for you) a partner with a compatible background and interests. Non-Western cultures, where people rate love as less important for marriage, do have lower divorce rates (Levine et al., 1995).

One key to a gratifying and enduring relationship is **equity**. When equity exists—when both partners receive in proportion to what they give—their chances for sustained and satisfying companionate love have been good (Gray-Little & Burks, 1983; Van Yperen & Buunk, 1990). In one national survey, "sharing household chores" ranked third, after "faithfulness" and a "happy sexual relationship," on a list of nine things people associated with successful marriages. As the Pew Research Center (2007) summarized, "I like hugs. I like kisses. But what I really love is help with the dishes."

equity

a condition in which people receive from a relationship in proportion to what they give to it.



HI & LOIS
I THINK I'M REALLY IN LOVE THIS TIME
HOW CAN YOU TELL?
WHENEVER I'M WITH HER, I GET ALL CLAMMY AND SWEATY AND NAUSEOUS AND DIZZY

YEP! THAT'S THE REAL THING

HI & LOIS © 1990 by King Features Syndicate, Inc.

Equity's importance extends beyond marriage. Mutually sharing one's self and possessions, making decisions together, giving and getting emotional support, promoting and caring about each other's welfare—all of these acts are at the core of every type of loving relationship (Sternberg & Grajek, 1984). It's true for lovers, for parent and child, and for close friends.

Sharing includes **self-disclosure**, revealing intimate details about ourselves—our likes and dislikes, our dreams and worries, our proud and shameful moments. "When I am with my friend," noted the Roman statesman Seneca, "me thinks I am alone, and as much at liberty to speak anything as to think it." Self-disclosure breeds liking, and liking breeds self-disclosure (Collins & Miller, 1994). As one person reveals a little, the other reciprocates, the first then reveals more, and on and on, as friends or lovers move to deeper levels of intimacy (Baumeister & Bratslavsky, 1999).

self-disclosure

the act of revealing intimate aspects of ourselves to others.

2430/Getty Images

Love is an ancient thing This 5000- to 6000-year-old “Romeo and Juliet” young couple was unearthed locked in embrace, near Rome.

One experiment marched some student pairs through 45 minutes of increasingly self-disclosing conversation—from “What is the greatest accomplishment of your life?” to “When did you last cry in front of another person? By yourself?” Other pairs spent the time with small-talk questions, such as “What was your high school like?” (Aron et al., 1997). By the experiment’s end, those experiencing the escalating intimacy felt much closer to their conversation partner than did the small-talkers. Likewise, after dating couples spent 45 minutes answering such questions, they felt increased love (Welker et al., 2014).

In addition to equity and self-disclosure, a third key to enduring love is *positive support*. Relationship conflicts are inevitable, but hurtful communications are not. Do we more often express sarcasm or support, scorn or sympathy, sneers or smiles? For unhappy couples, disagreements, criticisms, and put downs are routine. For happy couples in enduring relationships, positive interactions (compliments, touches, laughing) outnumber negative interactions (sarcasm, disapproval, insults) by at least 5 to 1 (Gottman, 2007; see also Sullivan et al., 2010).

In the mathematics of love, self-disclosing intimacy + mutually supportive equity = enduring companionate love.

Check Your Understanding

Ask Yourself

- When you think of some of the older couples you know, which ones seem to experience companionate love? How do you think they've achieved it?

Test Yourself

- How does the two-factor theory of emotion help explain *passionate love?*
- Two vital components for maintaining companionate love are _______________ and _______________-_______________.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 79 REVIEW

79-1 Why do we befriend or fall in love with some people but not others?

- Proximity (geographical nearness) increases liking, in part because of the *mere exposure effect*—exposure to novel stimuli increases liking of those stimuli.
- Physical attractiveness increases social opportunities and improves the way we are perceived.
- Similarity of attitudes and interests greatly increases liking, especially as relationships develop. We also like those who like us.

79-2 How does romantic love typically change as time passes?

- Intimate love relationships start with *passionate love*—an intensely aroused state.
- Over time, the strong affection of *companionate love* may develop, especially if enhanced by an *equitable* relationship, by intimate *self-disclosure*, and positive support.

Multiple-Choice Questions

1. Which of the following terms describes our geographic nearness to another person?

a. Mere exposure effect
b. Proximity
c. Similarity
d. Intimacy
e. Symmetry

2. Which of the following is an example of the mere exposure effect?

a. Adrianna has started arriving tardy to her second period class to avoid a group of kids in the hall who constantly tease her.

b. Abe has biked the same route to school so many times that he no longer has to think about where to turn.
c. Daiyu has seen the same toothpaste ad on television a hundred times. Each time she sees it she hates it more.
d. Abdul has always loved dogs, so he adopted one from the local shelter.
e. Guiren didn’t like sushi the first couple of times he tried it, but his friend encouraged him to keep eating it and now it’s one of his favorite foods.

3. Lisa and Nate are on their first date at a local restaurant. Which of the following is the best predictor of whether they will have a second date?

a. How physically attractive they find each other
b. If they both have successful careers
c. If they are of the same religion
d. If they met using an online dating service
e. If they have a shared desire to have children one day

4. Over time,

a. passionate and companionate love both decrease.
b. passionate love increases and companionate love decreases.
c. passionate and companionate love both increase.
d. passionate love decreases and companionate love increases.
e. there is no consistent relationship between the levels of passionate love and companionate love.

Practice FRQs

1. Describe one key factor present in passionate love and two key factors present in companionate love.

Answer

1 point: Physical arousal is the key factor that accompanies passionate love. [Page 812](#)

1 point: Equity—when people receive from a relationship in proportion to what they put into it—is one key component of companionate love. [Page 813](#)

1 point: Self-disclosure—revealing intimate aspects of yourself to others—is another key component of companionate love. [Page 814](#)

2. Matt has just finished a five-mile run with his new friend Janelle. How might the following influence him to ask her for a date?

- Similarity
- Two-factor theory of emotion
- Proximity

(3 points)

Module **80 Altruism, Conflict, and Peacemaking**

LEARNING TARGETS

- 80-1 Define *altruism*, and describe when people are most—and least—likely to help.
- 80-2 Discuss how social exchange theory and social norms explain helping behavior.
- 80-3 Explain how social traps and mirror-image perceptions fuel social conflict.
- 80-4 Discuss how we can promote peace.

Altruism

80-1 What is *altruism?* When are people most—and least—likely to help?

Altruism is an unselfish concern for the welfare of others. In rescuing his jailer, Dirk Willems (who we met in Unit XIV's beginning) exemplified altruism. Willems fits the definition of a *hero*—moral, courageous, and protective of those in need (Kinsella et al., 2015). Carl Wilkens and Paul Rusesabagina displayed another heroic example of altruism in Kigali, Rwanda. Wilkens, a Seventh-day Adventist missionary, was living there in 1994 with his family when militia from the Hutu ethnic group began to slaughter members of a minority ethnic group, the Tutsis. The U.S. government, church leaders, and friends all implored Wilkens to leave. He refused. After evacuating his family, and after every other American had left Kigali, he alone stayed and contested the 800,000-person genocide. When the militia came to kill him and his Tutsi servants, Wilkens' Hutu neighbors deterred them. Despite repeated death threats, he spent his days running roadblocks to take food and water to orphanages and to negotiate, plead, and bully his way through the bloodshed, saving lives time and again. "It just seemed the right thing to do," he later explained (Kristof, 2004).

altruism

unselfish regard for the welfare of others.

Elsewhere in Kigali, Rusesabagina, a Hutu married to a Tutsi and the acting manager of a luxury hotel, was sheltering more than 1200 terrified Tutsis and moderate Hutus. When international peacekeepers abandoned the city and hostile militia threatened his guests in the "Hotel Rwanda" (as it came to be called in a 2004 movie), the courageous Rusesabagina began cashing in past favors. He bribed the militia and telephoned influential people abroad to exert pressure on local authorities, thereby sparing the lives of the hotel's occupants, despite the surrounding chaos. Both Wilkens and Rusesabagina were displaying altruism, an unselfish regard for the welfare of others.

> “*Probably no single incident has caused social psychologists to pay as much attention to an aspect of social behavior as Kitty Genovese's murder.*”
>
> *R. Lance Shotland (1984)*

Altruism became a major concern of social psychologists after an especially vile act. On March 13, 1964, a stalker repeatedly stabbed Kitty Genovese, then raped her as she lay dying outside her Queens, New York, apartment at 3:30 A.M. “Oh, my God, he stabbed me!” Genovese screamed into the early morning stillness. “Please help me!” Windows opened and lights went on as some neighbors heard her screams. Her attacker fled and then returned to stab and rape her again. Until it was too late, no one called police or came to her aid.

Bystander Intervention

Although initial reports of the Genovese murder overestimated the number of witnesses, the reports triggered outrage over the bystanders' apparent “apathy” and “indifference.” Rather than blaming the onlookers, social psychologists John Darley and Bibb Latané (1968b) attributed their inaction to an important situational factor—the presence of others. Given certain circumstances, they suspected, most of us might behave similarly. To paraphrase the French writer Voltaire, we all are guilty of the good we did not do.

After staging emergencies under various conditions, Darley and Latané assembled their findings into a decision scheme: We will help only if the situation enables us first to *notice* the incident, then to *interpret* it as an emergency, and finally to *assume responsibility* for helping (**Figure 80.1**). At each step, the presence of others can turn us away from the path that leads to helping.

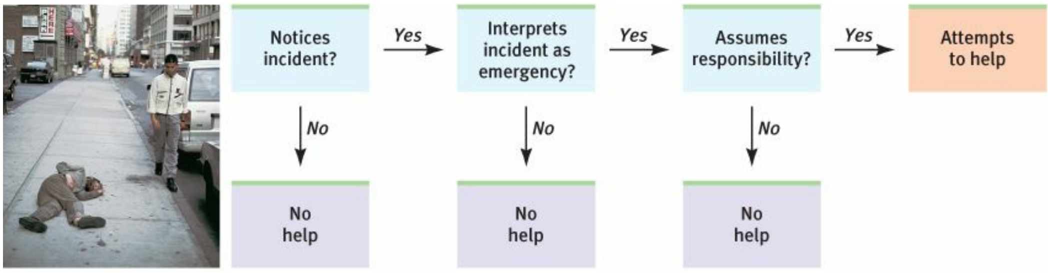

Figure 80.1

Figure 80.1 The decision-making process for bystander intervention

Before helping, one must first notice an emergency, then correctly interpret it, and then feel responsible. (Adapted from Darley & Latané, 1968b.)

One of Darley and Latané's experiments staged a fake emergency as students in separate laboratory rooms took turns talking over an intercom. Only the person whose microphone was switched on could be heard. When his turn came, one student (an accomplice of the experimenters) pretended to have an epileptic seizure, and he called for help (Darley & Latané, 1968a).

How did the others react? As **Figure 80.2** shows, those who believed only they could hear the victim—and therefore thought they alone were responsible for helping him—usually went to his aid. Students who thought others could also hear the victim's cries were more likely to do nothing. When more people shared responsibility for helping—when there was a *diffusion of responsibility*—any single listener was less likely to help. Inattention and diffused responsibility also contribute to the "global bystander nonintervention" as millions of far-away people die of hunger, disease, and genocide (Pittinsky & Diamante, 2015).

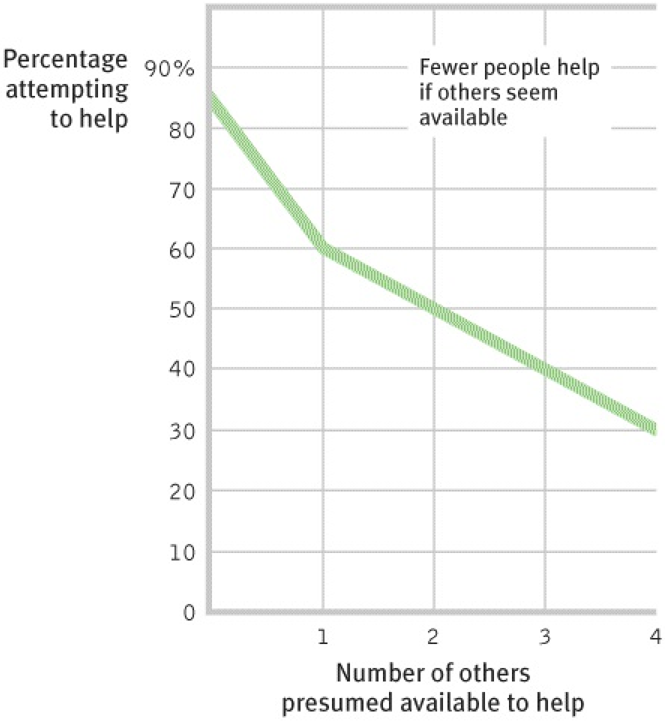

Figure 80.2
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from Darley & Latané, 1968a.

Figure 80.2 Responses to a simulated emergency

When people thought they alone heard the calls for help from a person they believed to be having an epileptic seizure, they usually helped. But when they thought four others were also hearing the calls, fewer than one-third responded.

Hundreds of additional experiments have confirmed this **bystander effect**. For example, researchers and their assistants took 1497 elevator rides in three cities and "accidentally" dropped coins or pencils in front of 4813 fellow passengers (Latané & Dabbs, 1975). When alone with the person in need, 40 percent helped; in the presence of 5 other bystanders, only 20 percent helped. The presence of bystanders reduces brain activation in the motor cortex, signaling that we don't need to take action (Hortenhuis & de Gelder, 2014).

bystander effect

the tendency for any given bystander to be less likely to give aid if other bystanders are present.

Observations of behavior in thousands of these situations—relaying an emergency phone call, aiding a stranded motorist, donating blood, picking up dropped books, contributing money, giving time—show that the odds of our helping someone depend on the characteristics of the person, the situation, and our own internal state. The odds of helping are highest when

- the person appears to need and deserve help.
- the person is in some way similar to us.
- the person is a woman.
- we have just observed someone else being helpful.
- we are not in a hurry.
- we are in a small town or rural area.
- we are feeling guilty.
- we are focused on others and not preoccupied.
- we are in a good mood.

PLEASE GIVE TO ALTRUISM RESEARCH
Nick Downes

© 2006 Nick Downes

This last result, that happy people are helpful people, is one of psychology’s most consistent findings. As poet Robert Browning (1868) observed, “Oh, make us happy and you make us good!” It doesn’t matter how we are cheered. Whether by being made to feel successful and intelligent, by thinking happy thoughts, by finding money, or even by receiving a posthypnotic suggestion, we become more generous and more eager to help (Carlson et al., 1988). And if our feeling of elevation follows witnessing or learning of someone else's self-giving deed, our helping will become even more pronounced (Schnall et al., 2010).

So happiness breeds helpfulness. But it's also true that helpfulness breeds happiness. Helping those in need activates brain areas associated with reward (Harbaugh et al., 2007; Kawamichi et al., 2015). That helps explain a curious finding: People who give money away are happier than those who spend it almost entirely on themselves. In one controlled experiment, researchers gave people an envelope with cash and instructed one group to spend it on themselves and another to spend it on others (Dunn et al., 2008; Dunn & Norton, 2013). Which group was happiest at the day's end? It was, indeed, those assigned to the spend-it-on-others condition. And in a survey of more than 200,000 people worldwide, people in both rich and poor countries were happier with their lives if they had donated to a charity in the last month. Just reflecting on an instance of spending money on others provides most people with a mood boost (Aknin et al., 2013).

Ask Yourself

- Imagine being a newcomer needing directions at a busy bus terminal. What could you do to increase the odds that someone would assist you, and what sort of person would be most likely to help?

Test Yourself

- Why didn't anybody help Kitty Genovese? What social psychology principle did this incident illustrate?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Helping—Self-Interest or Socialization?

80-2 How do social exchange theory and social norms explain helping behavior?

Why do we help? One widely held view is that self-interest underlies all human interactions, that our constant goal is to maximize rewards and minimize costs. Accountants call it *cost-benefit analysis*. Philosophers call it *utilitarianism*. Social psychologists call it **social exchange theory**. If you are considering donating blood, you may weigh the costs of doing so (time, discomfort, anxiety) against the benefits (reduced guilt, social approval, good feelings). If the rewards exceed the costs, you will help.

social exchange theory

the theory that our social behavior is an exchange process, the aim of which is to maximize benefits and minimize costs.

Others believe we help because we have been socialized to do so, through norms that prescribe how we *ought* to behave (Everett et al., 2015). Two such norms are the *reciprocity norm* and the *social-responsibility norm:*

The **reciprocity norm** is the expectation that we should return help, not harm, to those who have helped us. In our relations with others of similar status, this norm compels us to give (in favors, gifts, or social invitations) about as much as we receive. Sometimes this means “paying it forward,” as happened in one experiment, when people who were treated generously became more likely to be generous to a stranger (Tsvetkova & Macy, 2014). Returning favors feels good, making the norm of reciprocity a pleasant strategy to help others (Hein et al., 2016).

reciprocity norm

an expectation that people will help, not hurt, those who have helped them.

The reciprocity norm kicked in after Dave Tally, a Tempe, Arizona, homeless man, found $3300 in a backpack that an Arizona State University student had misplaced on his way to buy a used car (Lacey, 2010). Instead of using the cash for much-needed bike repairs, food, and shelter, Tally turned the backpack in to the social service agency where he volunteered. To reciprocate Tally's help, the backpack's owner thanked him with a reward. Hearing about Tally's self-giving deeds, dozens of others also sent him money and job offers.

The **social-responsibility norm** is the expectation that we should help those who need our help—young children and others who cannot give as much as they receive—even if the costs outweigh the benefits. Europeans are most welcoming of asylum seekers who are most vulnerable—those, for example, who have been tortured or have no surviving family (Bansak et al., 2016). Construction worker Wesley Autrey exemplified the social-responsibility norm on January 2, 2007. He and his 6- and 4-year-old daughters were awaiting a New York City subway train when, before them, a man collapsed in a seizure, got up, then stumbled to the platform's edge and fell onto the tracks. With train headlights approaching, "I had to make a split-second decision," Autrey later recalled (Buckley, 2007). His decision, as his girls looked on in horror, was to leap from the platform, push the man off the tracks and into a foot-deep space between them, and lay atop him. As the train screeched to a halt, five cars traveled just above his head, leaving grease on his knit cap. When Autrey cried out, "I've got two daughters up there. Let them know their father is okay," onlookers erupted into applause.

social-responsibility norm

an expectation that people will help those needing their help.

Many world religions encourage their followers to practice the social-responsibility norm, and sometimes this leads to prosocial behavior. Between 2006 and 2008, Gallup polls sampled more than 300,000 people across 140 countries, comparing the “highly religious” (who said religion was important to them and who had attended a religious service in the prior week) to those less religious. The highly religious, despite being poorer, were about 50 percent more likely to report having “donated money to a charity in the last month” and to have volunteered time to an organization (Pelham & Crabtree, 2008).

Nick Brooks/Newsday/AP Photo

Subway hero Wesley Autrey “I don’t feel like I did something spectacular; I just saw someone who needed help.” Five years later, a similar situation occurred when another man was shoved onto subway tracks—but this time, no one helped (Nocera, 2012). Social psychologists have wondered: Under what conditions will people help?

Conflict and Peacemaking

Positive social norms encourage generosity and enable group living. But conflicts often divide us. One response to recent mass migrations has been increasing nationalism and nativism. Moreover, *every day* the world continues to spend almost $5 billion for arms and armies—money that could be used for badly needed housing, nutrition, education, and health care. Knowing that wars begin in human minds, psychologists have wondered: What in the human mind causes destructive conflict? How might the perceived threats of social diversity be replaced by a spirit of cooperation?

Elements of Conflict

80-3 How do social traps and mirror-image perceptions fuel social conflict?

To a social psychologist, a **conflict** is a perceived incompatibility of actions, goals, or ideas. The elements of conflict are much the same, whether partners sparring, political groups feuding, or nations at war. In each situation, conflict may seed positive change, or be a destructive process that can produce unwanted results. Among these processes are *social traps* and *distorted perceptions*.

conflict

a perceived incompatibility of actions, goals, or ideas.

Social Traps

In some situations, pursuing our personal interests also supports our collective well-being. As capitalist Adam Smith wrote in *The Wealth of Nations* (1776), “It is not from the benevolence of the butcher, the brewer, or the baker that we expect our dinner, but from their regard to their own interest.” In other situations, we *harm* our collective well-being by pursuing our personal interests. Such situations are **social traps**.

social trap
a situation in which the conflicting parties, by each pursuing their self-interest rather than the good of the group, become caught in mutually destructive behavior.

Researchers have created mini social traps in laboratory games that require two participants to choose between pursuing their immediate self-interest, at others’ expense, versus cooperating for mutual benefits. Many real-life situations similarly pit our individual interests against our communal well-being. Individual fish trawlers reasoned that the fish they took would not threaten the species and that if they didn’t take them, others would anyway. The result: Some fish stocks have been depleted. Ditto for the buffalo hunters of yesterday and the elephant-tusk poachers of today. Individual car owners and home owners reason, “Electric cars are more expensive. Besides, the fuel that I burn in my one car doesn’t noticeably add to the greenhouse gases.” When enough people reason similarly, the collective result threatens disaster—climate change, rising seas, and more extreme weather.

Social traps challenge us to reconcile our right to pursue our personal well-being with our responsibility for the well-being of all. Psychologists have therefore explored ways to convince people to cooperate for their mutual betterment—through agreed-upon *regulations*, through better *communication*, and through promoting *awareness* of our responsibilities toward community, nation, and the whole of humanity (Dawes, 1980; Linder, 1982; Sato, 1987). Given effective regulations, communication, and awareness, people more often cooperate, whether playing a laboratory game or the real game of life.

Enemy Perceptions

Psychologists have noted that those in conflict have a curious tendency to form diabolical images of one another. These distorted images are, ironically, so similar that we call them **mirror-image perceptions**: As we see “them”—as untrustworthy, with evil intentions—so “they” see us. Each demonizes the other. My political party has benevolent motives; the other party is malevolent (Waytz et al., 2014).

mirror-image perceptions

mutual views often held by conflicting people, as when each side sees itself as ethical and peaceful and views the other side as evil and aggressive.

Mirror-image perceptions can often feed a vicious cycle of hostility. If Juan believes Maria is annoyed with him, he may snub her, causing her to act in ways that justify his perception. As with individuals, so with countries. Perceptions can become **self-fulfilling prophecies**—beliefs that confirm themselves by influencing the other country to react in ways that seem to justify them.

self-fulfilling prophecy

a belief that leads to its own fulfillment.

Individuals and nations alike tend to see their own actions as responses to provocation, not as the causes of what happens next. Perceiving themselves as returning tit for tat, they often hit back harder, as University College London volunteers did in one experiment (Shergill et al., 2003). Their task: After feeling pressure on their own finger, they were to use a mechanical device to press on another volunteer’s finger. Although told to reciprocate with the same amount of pressure, they typically responded with about 40 percent more force than they had just experienced. Despite seeking only to respond in kind, their touches soon escalated to hard presses, much as when each child after a fight claims that “I just poked him, but he hit me harder.”

Mirror-image perceptions feed similar cycles of hostility on the world stage. To most people, torture seems more justified when done by “us” rather than “them” (Tarrant et al., 2012). In American media reports, Muslims who kill have been portrayed as fanatical, hateful terrorists, while an American who allegedly killed 16 Afghans was portrayed as stressed out from marriage problems, four tours of duty, and a friend’s having had his leg blown off (Greenwald, 2012).

The point is not that truth must lie midway between two such views (one may be more accurate). The point is that enemy perceptions often form mirror images. Moreover, as enemies change, so do perceptions. In American minds and media, the “bloodthirsty, cruel, treacherous” Japanese of World War II later became our “intelligent, hardworking, self-disciplined, resourceful allies” (Gallup, 1972).

Promoting Peace

80-4 What can we do to promote peace?

How can we make peace? Can contact, cooperation, communication, and conciliation transform the antagonisms fed by prejudice and conflicts into attitudes that promote peace? Research indicates that, in some cases, they can.

Contact

Does it help to put two conflicting parties into close contact? It depends. Negative contact increases *dis*liking (Graf et al., 2014; Paolini et al., 2014). But positive contact—especially noncompetitive contact between parties of equal status, such as fellow store clerks—typically helps. Initially prejudiced co-workers of different races have, in such circumstances, usually come to accept one another. This finding is confirmed by a statistical digest of more than 500 studies of face-to-face contact between majority people and outgroups (such as ethnic minorities, older and LGBTQ people, and people with disabilities). Among the quarter-million people studied across 38 nations, contact has correlated with (and in experiments has led to) more positive attitudes (Al Ramiah &

Hewstone, 2013; Lemmer & Wagner, 2015; Pettigrew & Tropp, 2011). Some examples:

- With cross-racial contact, South Africans' interracial attitudes have moved "into closer alignment" (Dixon et al., 2007; Finchilescu & Tredoux, 2010; Swart et al., 2011).
- Heterosexuals' attitudes toward gay people are influenced not only by *what* they know but also by *whom* they know (Collier et al., 2012; Smith et al., 2009). In surveys, the reason people most often give for becoming more supportive of same-sex marriage is "having friends, family, or acquaintances who are gay or lesbian" (Pew, 2013b). And in the United States, where attitudes toward gays have become more positive, 87 percent of people now say they know someone who is gay (Pew, 2016).
- Friendly contact, say between Blacks and Whites as roommates, improves attitudes toward others of the different race, and even toward other racial groups (Gaither & Sommers, 2013; Tausch et al., 2010).

However, contact is not always enough. In many schools, ethnic groups segregate themselves in lunchrooms, in classrooms, and elsewhere on school grounds (Alexander & Tredoux, 2010; Clack et al., 2005; Schofield, 1986). People in each group often think that they would welcome more contact with the other group, but they assume the other group does not reciprocate the wish (Richeson & Shelton, 2007). "I don't reach out to them, because I don't want to be rebuffed; they don't reach out to me, because they're just not interested." When such mirror-image misperceptions are corrected, friendships may form and prejudices melt.

Cooperation

To see if enemies could overcome their differences, researcher Muzafer Sherif (1966) set a conflict in motion. He separated 22 Oklahoma City boys into two separate camp areas. Then he had the two groups compete for prizes in a series of activities. Before long, each group became intensely proud of itself and hostile to the other group's "sneaky," "smart-alecky stinkers." Food wars broke out. Cabins were ransacked. Fistfights had to be broken up by camp counselors. Brought together, the two groups avoided each other, except to taunt and threaten. Little did they know that within a few days, they would be friends.

> “*You cannot shake hands with a clenched fist.*”
>
> *Indira Gandhi, 1971*

Sherif accomplished this by giving them **superordinate goals**—shared goals that could be achieved only through cooperation. When he arranged for the camp water supply to “fail,” all 22 boys had to work together to restore the water. To rent a movie in those pre-Netflix days, they all had to pool their resources. To move a stalled truck, the boys needed to combine their strength, pulling and pushing together. Having used isolation and competition to make strangers into enemies, Sherif used shared predicaments and goals to turn enemies into friends. What reduced conflict was not mere contact, but *cooperative* contact. Cooperative actions produce positive attitudes.

superordinate goals

shared goals that override differences among people and require their cooperation.

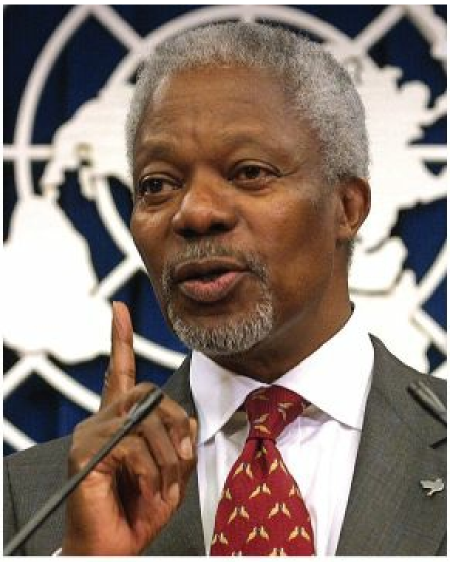
A shared predicament likewise can have a powerfully unifying effect on other groups as well. Children and youth exposed to war, and minority group members facing rejection or discrimination, likewise develop strong ingroup identification (Bauer et al., 2014; Ramos et al., 2012). Israeli children growing up in conflict areas often develop a conflict-supportive narrative of perceptions, beliefs, and emotions regarding their shared adversary (Nasie et al., 2016). Such narratives build ingroup solidarity but also insensitivity to the pain experienced by outgroup members (Levy et al., 2016).

> “*Me against my brother, my brothers and me against my cousins, then my cousins*

and me against strangers.”

Bedouin proverb

In the aftermath of a divisive political primary election, party members will usually reunify when facing their shared threat—the opposition party candidate. At such times, cooperation can lead people to define a new, inclusive group that dissolves their former subgroups (Dovidio & Gaertner, 1999). If this were a social psychology experiment, you might seat members of two groups not on opposite sides, but alternately around a table. Give them a new, shared name. Have them work together. Then watch “us” and “them” become “we.” After 9/11, one 18-year-old New Jersey man described this shift in his own social identity: “I just thought of myself as Black. But now I feel like I’m an American, more than ever” (Sengupta, 2001). In an actual experiment, White Americans who read a newspaper article about a terrorist threat against all Americans subsequently expressed reduced prejudice against Black Americans (Dovidio et al., 2004).



Shawn Baldwin/AP Photo

Kofi Annan “Most of us have overlapping identities which unite us with very different groups. We *can* love what we are, without hating what—and who—we are *not*. We can thrive in our own tradition, even as we learn from others” (Nobel Peace Prize lecture, 2001).

If cooperative contact between rival group members encourages positive attitudes, might this principle bring people together in multicultural schools? Could cooperative learning in classrooms create interracial friendships, while also enhancing student achievement? Experiments with adolescents from 11 countries confirm that the answer is *Yes* (Roseth et al., 2008). In the classroom as in the sports arena, members of interracial groups who work together on projects typically come to feel friendly toward one another. Knowing this, thousands of teachers have made interracial cooperative learning part of their classroom experience.

The power of cooperative activity to make friends of former enemies has led psychologists to urge increased international exchange and cooperation. Some experiments have found that just imagining the shared threat of global climate change reduces international hostilities (Pyszczynski et al., 2012). From adjacent Brazilian tribes to European countries, formerly conflicting groups have managed to build interconnections, interdependence, and a shared social identity as they seek common goals (Fry, 2012). As we engage in mutually beneficial trade, as we work to protect our common destiny on this fragile planet, and as we become more aware that our hopes and fears are shared, we can transform misperceptions that feed conflict into feelings of solidarity based on common interests.

ROCK BRIDGE

Grant Hindsley/AP Photo

Superordinate goals override differences Cooperative efforts to achieve shared goals are an effective way to break down social barriers.

Communication

When real-life conflicts become intense, a third-party mediator—a marriage counselor, labor mediator, diplomat, community volunteer—may facilitate much-needed communication (Rubin et al., 1994). Mediators help each party voice its viewpoint and understand the other's needs and goals. If successful, mediators can replace a competitive *win-lose* orientation with a cooperative *win-win* orientation that leads to a mutually beneficial resolution. A classic example: Two friends, after quarreling over an orange, agreed to split it. One squeezed his half for juice. The other used the peel from her half to flavor a cake. If only the two had communicated their motives to one another, they could have hit on the win-win solution of one having all the juice, the other all the peel.

Conciliation

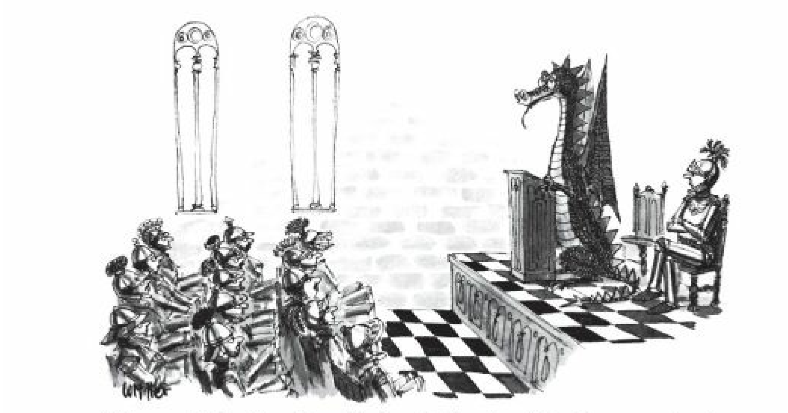
Understanding and cooperative resolution are most needed, yet least likely, in times of anger or crisis (Bodenhausen et al., 1994; Tetlock, 1988). When conflicts intensify, images become more stereotyped, judgments more rigid, and communication more difficult, or even impossible. Each party is likely to threaten, coerce, or retaliate. In the weeks before the 1990 Gulf War, the first President George Bush threatened, in the full glare of publicity, to "kick Saddam's ass." Saddam Hussein communicated in kind, threatening to make Americans "swim in their own blood."

Under such conditions, is there an alternative to war or surrender? Social psychologist Charles Osgood (1962, 1980) advocated a strategy of *Graduated and Reciprocated Initiatives in Tension-Reduction*, nicknamed **GRIT**. In applying GRIT, one side first announces its recognition of mutual interests and its intent to reduce tensions. It then initiates one or more small, conciliatory acts. Without weakening one's retaliatory capability, this modest beginning opens the door for reciprocity by the other party. Should the enemy respond with hostility, one reciprocates in kind. But so, too, with any conciliatory response.

GRIT

Graduated and Reciprocated Initiatives in Tension-Reduction—a strategy designed to decrease international tensions.

In laboratory experiments, small conciliatory gestures—a smile, a touch, a word of apology—have allowed both parties to begin edging down the tension ladder to a safer rung where communication and mutual understanding can begin (Lindskold, 1978; Lindskold & Han, 1988). In a real-world international conflict, U.S. President John F. Kennedy's gesture of stopping atmospheric nuclear tests began a series of reciprocated conciliatory acts that culminated in the 1963 atmospheric test-ban treaty.



Warren Miller The New Yorker Collection/The Cartoon Bank

"To begin with, I would like to express my sincere thanks and deep appreciation for the opportunity to meet with you. While there are still profound differences between us, I think the very fact of my presence here today is a major breakthrough."

As working toward shared goals reminds us, we are more alike than different. Civilization advances not by conflict and cultural isolation, but by tapping the knowledge, the skills, and the arts that are each culture's legacy to the whole human race. Thanks to cultural sharing, our modern society has been enriched by our cultural mix (Sowell, 1991). We have China to thank for paper and printing and for the magnetic compass that opened the great explorations. We have Egypt to thank for trigonometry. We have the Islamic world and India's Hindus to thank for our Arabic numerals. While celebrating and claiming these diverse cultural legacies, we can also welcome the continuing enrichment of today's cultural diversity. We can view ourselves as instruments in a human orchestra. And we can therefore each affirm our own culture's heritage while building bridges of communication, understanding, and cooperation across our cultural traditions.

✓ Check Your Understanding

Ask Yourself

- Do you regret not getting along with some friend or family member? How might you resolve the conflict using concepts you have just learned?

Test Yourself

- Why do sports fans tend to feel a sense of satisfaction when their archrival team loses? Why do such feelings, in other settings, make conflict resolution more challenging?
- What are some ways to reconcile conflicts and promote peace?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

* * *

If you just finished reading this book, your AP® course introduction to psychological science is nearly complete. Our tour of psychological science has taught us much—and you, too?—about our moods and memories, about the reach of our unconscious, about how we flourish and struggle, about how we perceive our physical and social worlds, and about how our biology and culture shape us. Our hope, as your guides on this tour, is that you have shared some of our fascination, grown in your understanding and compassion, and sharpened your critical thinking. And we hope you enjoyed the ride.

With every good wish in your future endeavors (including the AP® exam!),

Module 80 REVIEW

80-1 ***What is altruism?*** **When are people most—and least—likely to help?**

- *Altruism* is unselfish regard for the well-being of others.
- We are most likely to help when we (a) notice an incident, (b) interpret it as an emergency, and (c) assume responsibility for helping. Other factors, including our mood and our similarity to the victim, also affect our willingness to help.
- We are least likely to help if other bystanders are present (the *bystander effect*).

80-2 How do social exchange theory and social norms explain helping behavior?

- *Social exchange theory* is the view that we help others because it is in our own self-interest; in this view, the goal of social behavior is maximizing personal benefits and minimizing costs.
- Others believe that helping results from socialization, in which we are taught guidelines for expected behaviors in social situations, such as the *reciprocity norm* and the *social-responsibility norm.*

80-3 How do social traps and mirror-image perceptions fuel social conflict?

- A *conflict* is a perceived incompatibility of actions, goals, or ideas.
- *Social traps* are situations in which people in conflict pursue their own individual self-interest, harming the collective well-being.
- Individuals and cultures in conflict also tend to form *mirror-image perceptions:* Each party views the opponent as untrustworthy and evil-intentioned, and itself as an ethical, peaceful victim. Perceptions can

become *self-fulfilling prophecies.*

80-4 What can we do to promote peace?

- Peace can result when individuals or groups work together to achieve *superordinate* (shared) *goals.*
- Research indicates that four processes—contact, cooperation, communication, and conciliation—help promote peace.

Multiple-Choice Questions

1. Putting himself in danger, Nish stood up to the bullies who were beating up Neel in a display of

a. assuming responsibility.
b. mirror-image perceptions.
c. altruism.
d. the bystander effect.
e. diffusion of responsibility.

2. Sherif and his colleagues found that by providing hostile groups with ______, they were able to reduce tension as they worked together to solve problems.

a. superordinate goals
b. self-fulfilling prophecies
c. mirror-image perceptions
d. social traps
e. GRIT

3. A situation in which the conflicting parties, by rationally pursuing their self-interest, become caught in mutually destructive behavior is known as a

a. social trap.
b. conflict.
c. bystander effect.

d. diffusion of responsibility.
e. social-responsibility norm.

4. Lee feels that he cannot understand chemistry, so he gives up on doing the homework or studying for tests. When he fails chemistry he is demonstrating a(n)

a. superordinate goal.
b. mirror-image perception.
c. enemy perception.
d. social trap.
e. self-fulfilling prophecy.

Practice FRQs

1. According to Darley and Latané, what three things must happen for a bystander to intervene?

Answer

1 point: The bystander must notice the event. Page 817

1 point: The bystander must interpret the incident as an emergency. Page 817

1 point: The bystander must assume responsibility. Page 817

2. Several years from now, your best friend asks you to help move all of his furniture out of his parents' house into his new apartment. Explain how each of the following will play a role in deciding whether to help your friend move.

- Social exchange theory
- Reciprocity norm

(2 points)

AP® EXAM PRACTICE QUESTIONS

Multiple-Choice Questions

1. The enhancement of a group's prevailing tendencies occurs when people within a group discuss an idea that most of them either favor or oppose. What is this tendency called?

a. Group polarization
b. Deindividuation
c. The just-world phenomenon
d. Discrimination
e. Categorization

2. Caroline hates to do group projects with Jake because she ends up doing much more of the work than he does. Jake is engaging in

a. social facilitation.
b. a social trap.
c. social loafing.
d. self-disclosure.
e. altruism.

3. Samir does not feel any obligation to help the homeless people he sees each morning on the way to the subway. He assumes it is their fault that they are homeless and that they must have done something to deserve it. Samir's assumptions represent

a. a stereotype.
b. an ingroup bias.
c. altruism.
d. aggression.
e. the just-world phenomenon.

4. According to research on the bystander effect, which of the following people is most likely to stop and help a stranger?

a. Jacob is on his way to a doctor's appointment with his young son.
b. Xavier lives in a crowded city.

c. Malika is in a terrible mood, having just learned that she failed her midterm exam.
d. Ciera just saw a young girl offering her arm to help an older woman cross the street.
e. Mahmood is lost in thought as he walks to work, worrying about his upcoming presentation.

5. Students at Interlake High School believe they are superior to West Lake High School in every way possible. This is a demonstration of

a. ingroup bias.
b. conformity.
c. scapegoat theory.
d. discrimination.
e. groupthink.

6. People frequently blame internal dispositions for others' behavior according to

a. the foot-in-the-door phenomenon.
b. the fundamental attribution error.
c. attribution.
d. social psychology.
e. social thinking.

7. Geoff and Todd tried to buy tickets to see their favorite band, but they were unable to do so because the show sold out by the time they filled in the online form. Geoff swipes his laptop onto the floor in anger. The best explanation for why he does this is

a. the proximity effect.
b. GRIT.
c. the frustration-aggression principle.
d. social scripting.
e. deindividuation.

8. Galileo's notion that the earth revolved around the sun was in opposition to the widespread beliefs of his era. Over time, his ideas were accepted by more and more scholars. What social psychological principle is this an example of?

a. Social thinking
b. Group polarization
c. Conformity
d. A stereotype
e. Minority influence

9. Jackson downloaded an album, even though he liked only one of the songs. Over time he has found that he likes the other songs on the album as well. This is best explained by

a. the mere exposure effect.
b. hindsight bias.
c. aggression.
d. the just-world phenomenon.
e. the other-race effect.

0. The tension that occurs when we become aware that our attitudes and actions don’t coincide is known as

a. role playing.
b. the fundamental attribution error.
c. social pressure.
d. social influence.
e. cognitive dissonance.

1. A teacher offers her class the option of 3 or 10 points of extra credit. She explains that if most of the class ask for only 3 points, then they will all get the extra credit, but if most of the class asks for 10 points, then no one will earn any extra credit. Most of the students, hoping to gain more themselves and not thinking of the collective well-being of the class, ask for 10 points, and the whole class gets nothing. The class is demonstrating

a. GRIT.
b. the fundamental attribution error.

c. a social trap.
d. scapegoat theory.
e. discrimination.

2. Which of the following *least* describes prejudice?

a. An unjustifiable attitude toward a group
b. Schemas that influence how we notice and interpret events
c. Preconceived ideas that bias our impressions of others' behavior
d. A physical behavior intended to harm someone physically or emotionally
e. Automatic and unconscious thoughts and behaviors

3. Among the main factors that determine whether a relationship will form and last are

I. I. proximity.
II. II. financial status.
III. III. similarity.

a. I only
b. II only
c. III only
d. I & II only
e. I & III only

4. Becoming less self-conscious and less restrained when in a group situation is referred to as

a. social loafing.
b. deindividuation.
c. social facilitation.
d. obedience.
e. cognitive dissonance.

5. Carol believes that Paul is mad at her so she chooses to ignore him, which serves to actually make him mad at her. This is an example of

a. superordinate goals.

b. tension-reduction.
c. a social trap.
d. a mirror-image perception.
e. a self-fulfilling prophecy.

6. Which of the following is the most complete definition of conformity?

a. Sharing a mood with others
b. Unconsciously mimicking the behaviors and reactions of others
c. Changing thoughts about a situation in order to please an authority figure
d. Adjusting our behavior or thinking toward some group standard
e. Bringing our attitudes in line with our actions

7. People are more likely to disobey an authority figure when

a. they are alone with the authority figure.
b. the authority figure is male.
c. the authority figure’s request would cause harm to another person.
d. they are in a group with more than three people.
e. they have seen someone else disobey.

8. Tim pulls into traffic behind an older woman and immediately gets irritated because “old women can’t drive.” Tim’s belief is

a. a norm.
b. a stereotype.
c. the frustration-aggression principle.
d. a mirror-image perception.
e. discrimination.

9. After being married 50 years, Nancy and Bill feel a deep, affectionate attachment to each other after all that they have shared throughout their marriage. Psychologists would say that they have developed

a. passionate love.
b. a social script.
c. an ingroup bias.

d. companionate love.
e. GRIT.

0. Although most members of the faculty were strongly against the proposed new schedule, they did not voice their objections because two well-liked senior faculty members were in favor of the new schedule. This small group of dissenters were demonstrating

a. minority influence.
b. ingroup bias.
c. group polarization.
d. groupthink.
e. a norm.

Free-Response Questions

1. Abi moved from her small rural hometown to a large city to pursue her singing career. She was soon hired for an important and popular choral performance and was nervous but excited about this new opportunity. Explain how the following social psychology factors might affect her experiences in the “big city.”

- Self-fulfilling prophecy
- Frustration-aggression model
- Social facilitation
- Reciprocity norm

Rubric for Free Response Question 1

1 point: Self-fulfilling prophecy: Abi may think that she is not talented enough to compete with all of the other singers in the performance. Because of her low expectations of herself, she may not perform to the best of her ability. Page 820

1 point: Frustration-aggression model: If Abi does not progress to her satisfaction, and experiences frustration as her career stagnates, she may lash out at her colleagues either physically or verbally, or even try to sabotage others’ careers to further her own. Page 803

1 point: Social facilitation: Abi has been singing for a number of years. Because this is a well-practiced activity, Abi’s performance should be enhanced by the presence of others. Because she will have larger crowds in the “big city,” Abi’s performance should improve in front of larger crowds. Page 784

1 point: Reciprocity norm: If Abi receives gifts (such as flowers) from the audience, she may be motivated to give an extra effort in her performances. If the audience perceives that Abi is throwing herself completely into her performances, they may be more likely to applaud and cheer because the reciprocity norm indicates we will often return the efforts or feelings of others. Page 818

2. Ken has just taken a job with an organization that raises money to provide assistance to homeless veterans. Explain how Ken could use each of the following to increase donations.

- Foot-in-the-door phenomenon
- Central route persuasion
- Social responsibility norm
- Normative social influence
- Conformity

(5 points)

3. Dutch is in his first year as a student at a large university. At the urging of some friends, he attended a pep rally the night before the football game. At the rally, the marching band played the university’s fight song and Dutch began singing along as they did. The head football coach then gave a rousing speech, and Dutch joined with the hundreds of other students to cheer him. Although Dutch had not paid attention to the football team prior to the rally, he enthusiastically participated in the rally, even going so far as to have an image of the team’s mascot painted on his face. The following day, he attended the game and since has become an avid fan of the football team.

Analyze Dutch’s behavior at the rally and afterward, using each of the following principles of social psychology:

- Peripheral route persuasion
- Ingroup bias
- Social facilitation
- Deindividuation

(4 points)

81 Influences on Drug Use

82 Psychology at Work

83 Animal Thinking and Language

Module **81 Influences on Drug Use**

LEARNING TARGETS

- 81-1 Explain why some people become regular users of consciousness-altering drugs.

81-1 Why do some people become regular users of consciousness-altering drugs?

Drug use by North American youth increased during the 1970s. Then, with increased drug education and a more realistic and deglamorized media depiction of taking drugs, drug use declined sharply (except for a small rise in the mid-1980s). After the early 1990s, the cultural antidrug voice softened, and some drugs for a time were again glamorized in music and films. Consider, for example, historical trends in the use of marijuana:

- In the University of Michigan's annual survey of 15,000 U.S. high school seniors, the proportion who said there is "great risk" in regular marijuana use rose from 35 percent in 1978 to 79 percent in 1991, then retreated to 31 percent in 2016 (Johnston et al., 2017).
- After peaking in 1978, marijuana use by U.S. high school seniors declined through 1992, then rose, but has recently been holding steady (see **Figure 81.1**). Among Canadian 15- to 24-year-olds, 23 percent report using marijuana monthly, weekly, or daily (Health Canada, 2012).

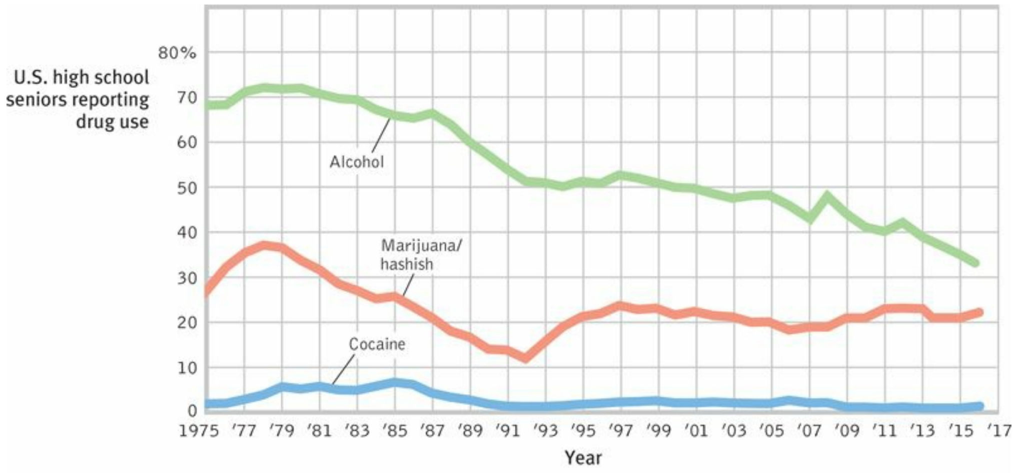

Figure 81.1
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from Johnston et al., 2017; Miech et al., 2016.

Figure 81.1 Trends in drug use

The percentage of U.S. high school seniors who said they had used alcohol, marijuana, or cocaine during the past 30 days largely declined from the late 1970s to 1992, when it partially rebounded for a few years.

For some adolescents, occasional drug use represents thrill seeking. Yet why do some adolescents, but not others, become regular drug users? In search of answers, researchers have engaged biological, psychological, and social-cultural levels of analysis.

FYI

Warning signs of alcohol use disorder:

- Drinking binges
- Craving alcohol
- Use results in unfulfilled work, school, or home tasks
- Failing to honor a resolve to drink less
- Continued use even when aware of risks involved
- Avoiding family or friends when drinking

Biological Influences

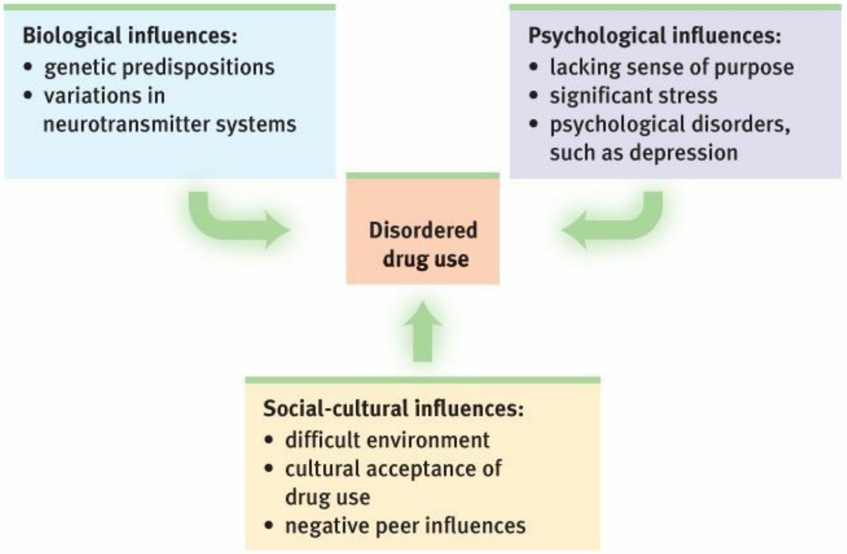
Some people may be biologically vulnerable to particular drugs. For example, evidence accumulates that heredity influences some aspects of substance use problems, especially those appearing by early adulthood (Crabbe, 2002):

- *Twin studies.* If an identical rather than fraternal twin is diagnosed with alcohol use disorder, the other twin is at increased risk for alcohol problems (Kendler et al., 2002). In marijuana use, too, identical twins more closely resemble each other than do fraternal twins.
- *Genetics research.* Researchers have identified genes associated with alcohol use disorder, and they are seeking genes that contribute to tobacco addiction (Stacey et al., 2012). These culprit genes seemingly produce deficiencies in the brain's natural dopamine reward system: While triggering temporary dopamine-produced pleasure, the addictive drugs disrupt normal dopamine balance. Studies of how drugs reprogram the brain's reward systems raise hopes for anti-addiction drugs that might block or blunt the effects of alcohol and other drugs (Miller, 2008; Wilson & Kuhn, 2005).
- *Adoption studies.* One study tracked 18,115 Swedish adoptees. Those with drug-abusing biological parents were at doubled risk of drug abuse, indicating a genetic influence. But then those with drug-abusing adoptive siblings also had a doubled risk of drug abuse, indicating an environmental influence (Kendler et al., 2012).

So, what might those environmental influences be?

Psychological and Social-Cultural Influences

Throughout this text, you have seen that biological, psychological, and social-cultural factors interact to produce behavior. So, too, with problematic drug use (**Figure 81.2**). One psychological factor that has appeared in studies of youth and young adults is the feeling that life is meaningless and directionless (Newcomb & Harlow, 1986). This feeling is common among school dropouts who subsist without job skills, without privilege, and with little hope.



Biological influences:
• genetic predispositions
• variations in neurotransmitter systems
Psychological influences:
• lacking sense of purpose
• significant stress
• psychological disorders, such as depression
Disordered drug use
Social-cultural influences:
• difficult environment
• cultural acceptance of drug use
• negative peer influences

Figure 81.2
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 81.2 Biopsychosocial approach

Researchers investigate disordered drug use from complementary perspectives.

Sometimes the psychological influence is obvious. Many heavy users of alcohol, marijuana, and cocaine have experienced significant stress or failure and are depressed. Girls with a history of depression, eating disorders, or sexual or physical abuse are at increased risk for problematic substance use. So are youth undergoing school or neighborhood transitions (CASA, 2003; Logan et al., 2002). By temporarily dulling their psychological pain, psychoactive drugs may offer a way to avoid coping with depression, anger, anxiety, or insomnia. (As Unit VI explained, behavior is often controlled more by its immediate consequences than by its later ones.)

Smoking usually begins during early adolescence. (If the cigarette manufacturers haven't made you their devoted customer by the time you reach college or university, they almost surely never will.) Adolescents, self-conscious and often thinking the world is watching their every move, are especially vulnerable to smoking's allure. They may first light up to imitate glamorous celebrities, to project a mature image, to handle stress, or to get the social reward of acceptance by other smokers (Cin et al., 2007; DeWall & Pond, 2011; Tickle et al., 2006). Mindful of these tendencies, cigarette companies have effectively modeled smoking with themes that appeal to youths: attractiveness, independence, adventurousness, peer approval (Surgeon General, 2012). Typically, teens who start smoking also have friends who smoke, who offer them cigarettes and describe the pleasure cigarettes bring (Rose et al., 1999). Among teens whose parents and best friends are nonsmokers, the smoking rate is close to zero (Moss et al., 1992; also see **Figure 81.3**).

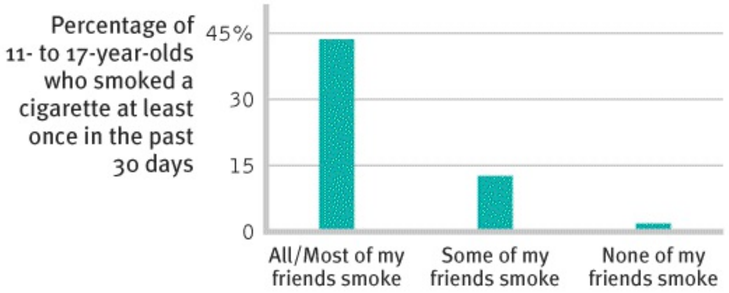


Figure 81.3
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 81.3 Peer influence

Kids seldom smoke if their friends don't (Philip Morris, 2003). A correlation-causation question: Does the close link between teen smoking and friends' smoking reflect peer influence? Teens seeking similar friends? Or both?

Rates of drug use also vary across cultural and ethnic groups. One survey of European teens found that lifetime marijuana use ranged from 5 percent in Norway to more than eight times higher in the Czech Republic

(Romelsjö et al., 2014). Independent U.S. government studies of drug use in households and among high schoolers nationwide reveal that African-American teens have sharply lower rates of drinking, smoking, and cocaine use (Johnston et al., 2007). Alcohol and other drug addiction rates have also been low among actively religious people, with extremely low rates among Orthodox Jews, Mormons, Mennonites, and the Amish (DeWall et al., 2014; Salas-Wright et al., 2012).

Pictorial Press Ltd/Alamy

Nic-A-Teen Virtually nobody starts smoking past the vulnerable teen years. Eager to hook customers whose addiction will give them business for years to come, cigarette companies target teens. Portrayals of smoking by popular actors, such as Scarlett Johansson in *Hail, Caesar!*, tempt teens to imitate.

Whether in cities or rural areas, peers influence attitudes about substance use. They also throw the parties and provide (or don't provide) the drugs. If an adolescent's friends use drugs, the odds are that he or she will, too. If the friends do not, the opportunity may not even arise. Teens who come from happy families, who do not begin drinking before age 15, and who do well in school tend not to use drugs, largely because they rarely associate with those who do (Bachman et al., 2007; Hingson et al., 2006; Odgers et al., 2008).

Peer influence is more than what friends do or say. Adolescents' expectations—what they *believe* friends are doing and favoring—influence their behavior (Vitória et al., 2009). One study surveyed sixth graders in

22 U.S. states. How many believed their friends had smoked marijuana? About 14 percent. How many of those friends acknowledged doing so? Only 4 percent (Wren, 1999). University students are not immune to such misperceptions: Drinking dominates social occasions partly because students overestimate their peers' enthusiasm for alcohol and underestimate their views of its risks (Miller & Prentice, 2016; Self, 1994) (**Table 81.1**). When students' overestimates of peer drinking are corrected, alcohol use often subsides (Moreira et al., 2009).

TABLE 81.1 Facts About "Higher" Education

• College and university students drink more alcohol than their nonstudent peers and exhibit 2.5 times the general population's rate of substance abuse.
• Fraternity and sorority members report nearly twice the binge-drinking rate of nonmembers.
• Since 1993, campus smoking rates have declined, alcohol use has been steady, and abuse of prescription opioids, stimulants, tranquilizers, and sedatives has increased, as has marijuana use.

Source: NCASA, 2007.

People whose beginning use of drugs was influenced by their peers are more likely to stop using when friends stop or their social network changes (Chassin & MacKinnon, 2015). One study that followed 12,000 adults over 32 years found that smokers tend to quit in clusters (Christakis & Fowler, 2008). Within a social network, the odds of a person quitting increased when a spouse, friend, or co-worker stopped smoking. Similarly, most soldiers who engaged in problematic drug use while in Vietnam ceased their drug use after returning home (Robins et al., 1974).

FYI

Percentage of adults drinking weekly or more has varied by country:

United States	30%
Canada	40%
Britain	58%

(Gallup Poll, from Moore, 2006)

As always with correlations, the traffic between friends' drug use and our own may be two-way: Our friends influence us. Social networks matter. But we also select as friends those who share our likes and dislikes.

What do the findings on drug use suggest for drug prevention and treatment programs? Three channels of influence seem possible:

- Educate young people about the long-term costs of a drug's temporary pleasures.
- Help young people find other ways to boost their self-esteem and discover their purpose in life.
- Attempt to modify peer associations or to "inoculate" youth against peer pressures by training them in refusal skills.

> *" Substance use disorders don't discriminate; they affect the rich and the poor; they affect all ethnic groups. This is a public health crisis, but we do have*

solutions.”

U.S. Surgeon General Vivek Murthy, 2016

People rarely abuse drugs if they understand the physical and psychological costs, feel good about themselves and the direction their lives are taking, and are in a peer group that disapproves of using drugs. These educational, psychological, and social-cultural factors may help explain why 26 percent of U.S. high school dropouts, but only 6 percent of those with a postgraduate education, report smoking (CDC, 2011).

✓ Check Your Understanding

Ask Yourself

- Drinking dominates parties when students overestimate other students’ enthusiasm for alcohol. What sorts of misperceptions exist at your high school?

Test Yourself

- Why do tobacco companies try so hard to get customers hooked as teens?
- Studies have found that people who begin drinking in their early teens are much more likely to develop alcohol use disorder than those who begin at age 21 or after. What possible explanations might there be for this correlation?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 81 REVIEW

81-1 Why do some people become regular users of consciousness-altering drugs?

- Some people may be biologically vulnerable to particular drugs, such as alcohol.
- Psychological factors (such as stress or depression) and social factors (such as peer pressure) combine to lead many people to experiment with drugs. Cultural and ethnic groups have differing rates of drug use.
- Each type of influence—biological, psychological, and social-cultural—offers a possible path for drug prevention and treatment programs.

Multiple-Choice Questions

1. Which of the following is most clearly a biological influence on disordered drug use?

a. Significant stress.
b. Variations in neurotransmitter systems.
c. An urban environment.
d. Peer influence.
e. A lack of purpose.

2. In studies that examine perceived rates of alcohol use, students

a. typically overestimate the percentage of fellow students who drink.
b. accurately estimate the percentage of fellow students who drink.
c. tend to slightly underestimate the percentage of fellow students who drink.
d. tend to greatly underestimate the percentage of fellow students who drink.
e. tend to be inaccurate in their estimates of the percentage of fellow students who drink, but there is no clear pattern to their inaccuracies.

Practice FRQ

1. Briefly explain one biological, one psychological, and one social-cultural influence on drug use.

(3 points)

Module **82 Psychology at Work**

LEARNING TARGETS

- 82-1 Explain the concept of *flow.*
- 82-2 Describe three key areas of study related to industrial-organizational psychology.
- 82-3 Discuss how personnel psychologists facilitate job seeking, employee selection, work placement, and performance appraisal.
- 82-4 Describe the role of organizational psychologists.
- 82-5 Examine some effective leadership techniques.
- 82-6 Discuss what cultural influences need to be considered when choosing an effective leadership style.
- 82-7 Describe human factors psychologists' work to create user-friendly machines and work settings.

For most people, to live is to work. Work is life's biggest waking activity. Work helps satisfy multiple needs. Work supports us, enabling food, water, and shelter. Work connects us, meeting our social needs. Work helps define us. Meeting someone for the first time and wondering about their identity, we may ask, "So, what do you do?"?"

But the answer may give us only a partial picture of a person's life. We have many motives beyond work, including the desire for family, friends, and hobbies. We also vary in our job satisfaction. On the day we leave the workforce, some of us will sadly bid our former employer farewell; others will bid our former employer good riddance. What factors influence our perceptions of work as an activity marked by frustration versus *flow,* as a necessary chore versus a meaningful calling, or as an opportunity to do the bare minimum versus maximize our potential?

Flow

82-1 What is *flow*?

Individuals across various occupations vary in their attitudes toward their work. Some view their work as a *job,* an unfulfilling but necessary way to make money. Others view their work as a *career,* an opportunity to advance from one position to a better position. The rest—those who view their work as a *calling,* a fulfilling and socially useful activity—report the highest satisfaction with their work and with their lives (Dik & Duffy, 2012; Wrzesniewski & Dutton, 2001; Wrzesniewski et al., 1997).

This finding would not surprise Mihaly Csikszentmihalyi [chick-SENT-me-hi] (1990, 1999). He observed that our quality of life increases when we are purposefully engaged. Between the anxiety of being overwhelmed and stressed, and the apathy of being underwhelmed and bored, lies a zone in which we experience **flow**. When was the last time you experienced flow? Perhaps you can recall being in a zoned-out flow state while texting or playing a video game. If so, then perhaps you can sympathize with the two Northwest Airlines pilots who in 2009 were so focused on their laptops that they missed their control tower’s messages. The pilots flew 150 miles past their Minneapolis destination—and lost their jobs.

flow

a completely involved, focused state, with diminished awareness of self and time; results from full engagement of our skills.

Csikszentmihalyi formulated the flow concept after studying artists who spent hour after hour painting or sculpting with focused concentration. Immersed in a project, they worked as if nothing else mattered, and then, when finished, they promptly forgot about it. The artists seemed driven less by external rewards—money, praise, promotion

—than by the intrinsic rewards of creating their art. Nearly 200 other studies confirm that *intrinsic motivation* enhances performance (Cerasoli et al., 2014).

Csikszentmihalyi studied dancers, chess players, surgeons, writers, parents, mountain climbers, sailors, and farmers. His research included Australians, North Americans, Koreans, Japanese, and Italians. Participants ranged in age from the teen years to the golden years. A clear principle emerged: It’s exhilarating to flow with an activity that fully engages our skills (Fong et al., 2015). Flow experiences boost our sense of self-esteem, competence, and well-being. Idleness may sound like bliss, but purposeful work enriches our lives. Busy people are happier (Hsee et al., 2010; Robinson & Martin, 2008). One research team interrupted people on about a quarter-million occasions (using a phone app), and found people’s minds wandering 47 percent of the time. They were, on average, happier when their mind was *not* wandering (Killingsworth & Gilbert, 2010).

FYI

Sometimes, notes Gene Weingarten (2002), a humorist knows “when to just get out of the way.” Here are some sample job titles from the U.S. *Department of Labor Dictionary of Occupational Titles*: Animal impersonator, human projectile, banana ripening-room supervisor, impregnator, impregnator helper, dope sprayer, finger waver, rug scratcher, egg smeller, bottom buffer, cookie breaker, brain picker, hand pouncer, bosom presser, and mother repairer.

Finding Your Own Flow, and Matching Interests to Work

Want to identify your own path to flow? You can start by pinpointing your strengths and the types of work that may prove satisfying and successful. Marcus Buckingham and Donald Clifton (2001) suggested asking yourself four questions.

1. What activities give me pleasure? Bringing order out of chaos? Playing host? Helping others? Challenging sloppy thinking?

2. What activities leave me wondering, “When can I do this again?” rather than, “When will this be over?”
3. What sorts of challenges do I relish? And which do I dread?
4. What sorts of tasks do I learn easily? And which do I struggle with?

FYI

Have you ever noticed that when you are immersed in an activity, time flies? And that when you are watching the clock, it seems to move more slowly? French researchers have confirmed that the more we attend to an event’s duration, the longer it seems to last (Couli et al., 2004).

You may find your skills engaged and time flying when teaching or selling or writing or cleaning or consoling or creating or repairing. If an activity feels good, if it comes easily, if you look forward to it, then look deeper. You’ll see your strengths at work (Buckingham, 2007). For a free (requires registration) assessment of your own strengths, take the “Brief Strengths Test” at AuthenticHappiness.sas.upenn.edu.

Erik Isakson/Tetra Images/Corbis

Life disrupted Playing and socializing online are ever-present sources of distraction. It takes energy to resist checking our phones, and time to refocus mental concentration after each disruption. Such frequent interruptions disrupt flow, so it’s a good idea to instead schedule regular breaks for checking our handheld devices.

The U.S. Department of Labor also offers a career interest questionnaire through its Occupational Information Network (O*NET). At MyNextMove.org/explore/ip you will need about 10 minutes to respond to 60 items, indicating how much you would like or dislike activities ranging from building kitchen cabinets to playing a musical instrument. You will then receive feedback on how strongly your responses reflect six interest types (Holland, 1996):

- *Realistic* (hands-on doers)
- *Investigative* (thinkers)
- *Artistic* (creators)
- *Social* (helpers, teachers)
- *Enterprising* (persuaders, deciders)
- *Conventional* (organizers)

Finally, depending on how much training you are willing to complete, you will be shown occupations that fit your interest pattern (selected from a national database of 900+ occupations).

> “*Find a job you love, and you’ll never work another day of your life.*”
>
> *Facebook hiring video, 2016*

Do what you love and you will love what you do. A career counseling science aims, first, to assess people’s differing values, personalities, and, especially, interests, which are remarkably stable (Dik & Rottinghaus, 2013). (Your job may change, but your interests today will likely still be your interests in 10 years.) Second, it aims to alert people to well-matched vocations—vocations with a good *person-environment fit*. One study assessed 400,000 high school students’ interests and then followed them over time. The take-home finding: “Interests uniquely predict academic and career success over and above cognitive ability and personality” (Rounds & Su, 2014). Sixty other studies confirm the point both for students in school and workers on the job: Interests predict both performance and persistence (Nye et al., 2012). Lack of job fit can fuel frustration, resulting in unproductive and even hostile work behavior (Harold et al., 2016). One fee-based online service, jobzology.com, was developed by I/O psychologists to implement career counseling science. First, it assesses people’s interests, values, personalities, and workplace culture preferences. It then suggests occupations and connects them to job listings.

Industrial-Organizational Psychology

82-2 What are three key areas of study related to industrial-organizational psychology?

In developed nations work has expanded, from farming to manufacturing to *knowledge work*. More and more work is *outsourced* to temporary employees and consultants, or to workers telecommuting from off-site workplaces (Allen et al., 2015). (This book and its teaching package are developed and produced by a team of people in a dozen cities, from Alberta to Florida.) As work has changed, have our attitudes toward our work also changed? Has our satisfaction with work increased or decreased? Has the *psychological contract*—the sense of mutual obligations between workers and employers—become more or less trusting and secure? These are among the questions that fascinate **industrial-organizational (I/O) psychologists** as they apply psychology's principles to the workplace (**Table 82.1**).

industrial-organizational (I/O) psychology

the application of psychological concepts and methods to optimizing human behavior in workplaces.

TABLE 82.1 I/O Psychology and Human Factors Psychology at Work As scientists, consultants, and management professionals, industrial-organizational (I/O) psychologists may be found helping organizations to resolve work-family conflicts, build employee retention, address organizational climate, or promote team work. Human factors psychologists contribute to safety and improved designs.

Personnel Psychology: Maximizing Human Potential	Organizational Psychology: Building Better Organizations

	Human Factors Psychology
	• Designing optimum work environments • Optimizing person-machine interactions • Developing systems technologies

Information from the Society of Industrial and Organizational Psychology. For more information about I/O psychology and related job opportunities, visit siop.org.

The I/O psychology subfield of **personnel psychology** applies psychology’s methods and principles to selecting, placing, training, and evaluating workers. Personnel psychologists match people with jobs, by identifying and placing well-suited candidates. The I/O psychology subfield of **organizational psychology** considers how work environments and management styles influence worker motivation, satisfaction, and productivity. It focuses on modifying jobs and supervision in ways that boost morale and productivity.

personnel psychology

an I/O psychology subfield that helps with job seeking, and with employee recruitment, selection, placement, training, appraisal, and development.

organizational psychology

an I/O psychology subfield that examines organizational influences on worker satisfaction and productivity and facilitates organizational change.

Human factors psychology, now a distinct field allied with I/O psychology, explores how machines and environments can be optimally designed to fit human abilities. Human factors psychologists study people’s natural perceptions and inclinations to create user-friendly machines and work settings.

human factors psychology

a field of psychology allied with I/O psychology that explores how people and machines interact and how machines and physical environments can be made safe and easy to use.

In column 3: Danielle Slevens in Massachusetts, Betty Probert in Florida, and Christine Brune in Washington, DC.

Personnel Psychology

82-3 How do personnel psychologists facilitate job seeking, employee selection, work placement, and performance appraisal?

Psychologists assist organizations at various stages of selecting and assessing employees. They may help identify needed job skills, develop effective selection methods, recruit and evaluate appropriate applicants, introduce and train new employees, and appraise their performance. They also help job seekers. Across four dozen studies, training programs (which teach job-search skills, improve self-presentation, boost self-confidence, promote goal setting, and enlist support) have nearly tripled job seekers' success (Liu et al., 2014).

Using Strengths for Successful Selection

As a new AT&T human resources executive, psychologist Mary Tenopyr (1997) was assigned to solve a problem: Customer-service representatives were failing at a high rate. After concluding that many of the hires were ill-matched to the demands of their new job, Tenopyr developed a new selection instrument:

1. She asked new applicants to respond to various test questions (without as yet making any use of their responses).
2. She followed up later to assess which of the applicants excelled on the job.
3. She identified the earlier test questions that best predicted success.

The happy result of her data-driven work was a new test that enabled AT&T to identify likely-to-succeed representatives. Personnel selection techniques such as this one aim to recruit people with the kind of strengths that will enable them and their organization to flourish. Marry the strengths of people with the tasks of organizations and the result is often prosperity and profit.

Do Interviews Predict Performance?

Employee selection usually includes an interview. And many interviewers feel confident of their ability to predict long-term job performance from a get-acquainted *(unstructured)* interview. What's therefore shocking is how error-prone interviewers' predictions may be when predicting job or graduate school success. From their review of 85 years of personnel-selection research, I/O psychologists Frank Schmidt and John Hunter (1998; Schmidt, 2002) determined that for all but less-skilled jobs, general mental ability best predicts on-the-job performance. Subjective overall evaluations from informal interviews are more useful than handwriting analysis (which is worthless). But informal interviews are less informative than aptitude tests, work samples, job knowledge tests, and past job performance. After studying thousands of informal interviews and later job success, Google found "zero relationship. It's a complete random mess" (Bock, 2013). *Structured interviews,* however, can produce more accurate predictions.

Unstructured Interviews and the Interviewer Illusion

Traditional, *unstructured interviews* can provide a sense of someone's personality—their expressiveness, warmth, and verbal ability, for example. But these informal interviews also give interviewees considerable power to control the impression they are making in the interview situation (Barrick et al., 2009). Why, then, do many interviewers have such faith in their ability to discern interviewees' fitness for a job? "I have excellent interviewing skills," I/O psychology consultants often hear, "so I don't need reference checking as much as someone who doesn't have my ability to read people." Overrating one's ability to predict people's futures is called the *interviewer illusion* (Dana et al., 2013; Nisbett, 1987). Five factors explain interviewers' overconfidence:

- **INTERVIEWERS PRESUME THAT PEOPLE ARE WHAT THEY SEEM TO BE IN THE INTERVIEW SITUATION.** An unstructured interview may create a false impression of a person's behavior toward others in different situations. Some interviewees may feign desired attitudes, others may be nervous. As personality psychologists explain—and as Module 74 explored—when meeting others, we discount the enormous influence of varying situations and mistakenly presume that what we see is what we will get. But research on everything from chattiness to conscientiousness reveals that how we behave reflects not only our enduring traits, but also the details of the particular situation (such as wanting to impress in a job interview).

- **INTERVIEWERS' PRECONCEPTIONS AND MOODS COLOR HOW THEY PERCEIVE INTERVIEWEES' RESPONSES** (Cable & Gilovich, 1998; Macan & Dipboye, 1994). If interviewers instantly like a person who perhaps is similar to themselves, they may interpret the person's assertiveness as indicating "confidence" rather than "arrogance." If told certain applicants have been prescreened, interviewers are disposed to judge them more favorably. Such interviewers are showing *confirmation bias*, which we learned about in Unit VII: They search for information that supports their preconceptions about a job candidate and ignore or distort contradictory evidence (Skov & Sherman, 1986).
- **INTERVIEWERS JUDGE PEOPLE RELATIVE TO THOSE INTERVIEWED JUST BEFORE AND AFTER THEM** (Simonsohn & Gino, 2013). If you are being interviewed for business or medical school, hope for a time when the other interviewees have been weak.
- **INTERVIEWERS MORE OFTEN FOLLOW THE SUCCESSFUL CAREERS OF THOSE THEY HAVE HIRED THAN THE SUCCESSFUL CAREERS OF THOSE THEY HAVE REJECTED.** This missing feedback prevents interviewers from getting a reality check on their hiring ability.
- **INTERVIEWS DISCLOSE THE INTERVIEWEE'S GOOD INTENTIONS, WHICH ARE LESS REVEALING THAN HABITUAL BEHAVIORS** (Ouellette & Wood, 1998). Intentions matter. People can change. But the best predictor of the person we will be is the person we have been. Compared with work-avoiding university students, those who engage in their tasks are more likely, a decade and more later, to be engaged workers (Salmela-Aro et al., 2009). In one forty-year study, responsible,

high-performing 12-year-old students tended to grow up to become successful, high-earning adult workers (Spengler et al., 2015). Wherever we go, we take ourselves along.

Hoping to improve prediction and selection, personnel psychologists have put people in simulated work situations, sought information on past performance, aggregated evaluations from multiple interviews, administered tests, and developed job-specific interviews.

Structured Interviews

Unlike casual conversation aimed at getting a feel for someone, **structured interviews** offer a disciplined method of collecting information. A personnel psychologist may analyze a job, script questions, and train interviewers. The interviewers then ask all applicants the same questions, in the same order, and rate each applicant on established scales.

structured interview

an interview process that asks the same job-relevant questions of all applicants, each of whom is rated on established scales.

In an unstructured interview, someone might ask, “How organized are you?” “How well do you get along with people?” or “How do you handle stress?” Street-smart applicants know how to score high: “Although I sometimes drive myself too hard, I handle stress by prioritizing and delegating, and leaving time for sleep and exercise.”

By contrast, structured interviews pinpoint strengths (attitudes, behaviors, knowledge, and skills) that distinguish high performers in a particular line of work. The process includes outlining job-specific situations and asking candidates to explain how they would handle them, and how they handled similar situations in their prior employment. “Tell me about a time when you were caught between conflicting demands, without time to accomplish both. How did you handle that?” In its interviews, Google has asked, “Give me an example of a time when you solved an analytically difficult problem” (Bock, 2013).

To reduce memory distortions and bias, the interviewer takes notes and makes ratings as the interview proceeds and avoids irrelevant and follow-up questions. The structured interview therefore feels less warm, but that can be explained to the applicant: “This conversation won’t typify how we relate to each other in this organization.”

A review of 150 findings revealed that structured interviews had double the predictive accuracy of unstructured interviews (Schmidt & Hunter, 1998; Wiesner & Cronshaw, 1988). Structured interviews also reduce bias, such as against overweight applicants (Kutcher & Bragger, 2004).

If, instead, we let our intuitions bias the hiring process, noted Malcolm Gladwell (2000, p. 86), then “all we will have done is replace the old-boy network, where you hired your nephew, with the new-boy network, where you hire whoever impressed you most when you shook his hand. Social progress, unless we’re careful, can merely be the means by which we replace the obviously arbitrary with the not so obviously arbitrary.”

To recap, personnel psychologists help train job seekers, and they assist organizations in analyzing jobs, recruiting well-suited applicants, and selecting and placing employees. They also appraise employees’ performance (**Figure 82.1**)—our next topic.

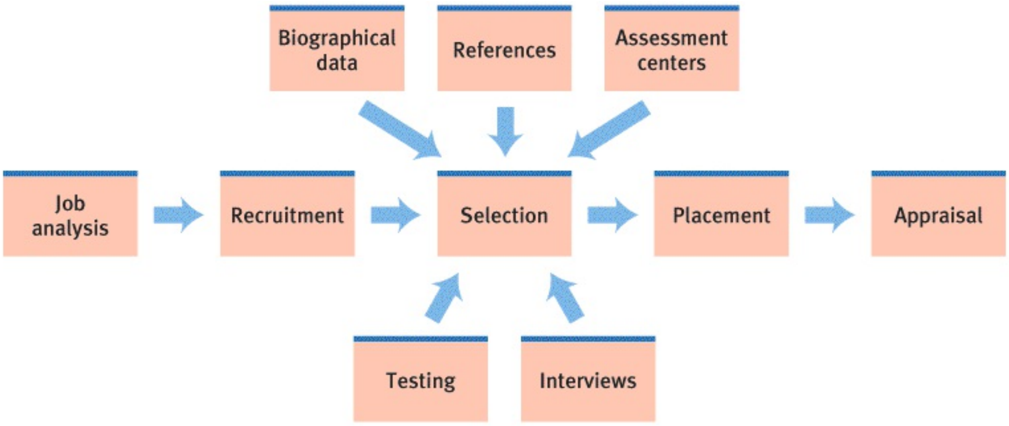

Figure 82.1

Figure 82.1 Personnel psychologists at work

Personnel psychologists consult in human resources activities, from job definition to recruitment to employee appraisal.

Appraising Performance

Performance appraisal serves organizational purposes: It helps decide who to keep on staff, how to appropriately reward and pay people, and how to better harness employee strengths, sometimes with job shifts or promotions. Performance appraisal also serves individual purposes: Feedback affirms workers' strengths and helps motivate needed improvements.

Performance appraisal methods include

- **CHECKLISTS** on which supervisors simply check specific behaviors that describe the worker ("always attends to customers' needs," "takes long breaks").
- **GRAPHIC RATING SCALES** on which a supervisor checks, perhaps on a five-point scale, how often a worker is dependable, productive, and so forth.
- **BEHAVIOR RATING SCALES** on which a supervisor checks scaled behaviors that describe a worker's performance. If rating the extent to which a worker "follows procedures," the supervisor might mark the employee somewhere between "often takes shortcuts" and "always follows established procedures" (Levy, 2003).

In some organizations, performance feedback comes not only from supervisors but also from all organizational levels. If you join an organization that practices *360-degree feedback* (**Figure 82.2**), you will rate yourself, your manager, and your other colleagues, and you will be rated by your manager, other colleagues, and customers (Green, 2002). The net result is often more open communication and more complete appraisal.

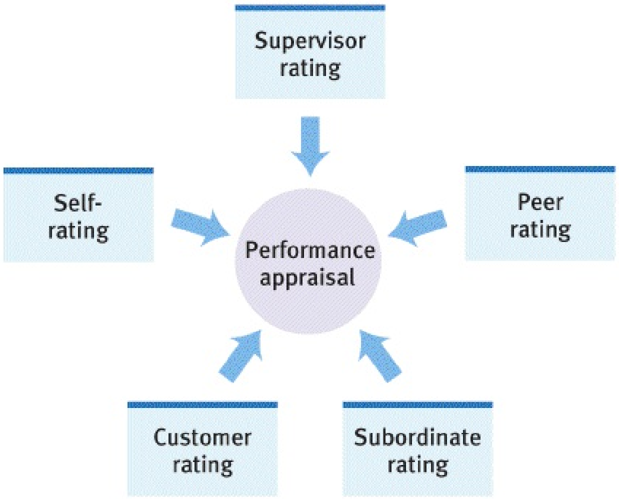

Figure 82.2
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers

Figure 82.2 360-degree feedback

With multisource 360-degree feedback, our knowledge, skills, and behaviors are rated by ourselves and surrounding others. University professors, for example, may be rated by their department chairs, their students, and their colleagues. After receiving all these ratings, professors discuss the 360-degree feedback with their department chair.

Performance appraisal, like other social judgments, is vulnerable to bias (Murphy & Cleveland, 1995). *Halo errors* occur when one's overall evaluation of an employee, or of a personal trait such as their friendliness, biases ratings of their specific work-related behaviors, such as their reliability. *Leniency* and *severity errors* reflect evaluators' tendencies to be either too easy or too harsh on everyone. *Recency errors* occur when raters focus only on easily remembered recent behavior. By using multiple raters and developing objective, job-relevant performance measures, personnel psychologists seek to support their organizations while also helping employees perceive the appraisal process as fair.

Check Your Understanding

Ask Yourself

- What have you learned about your own strengths and about the kind of career you might see yourself pursuing?

Test Yourself

- What is the value of finding flow in our work?
- A human resources director explains to you that “I don’t bother with tests or references. It’s all about the interview.” Based on I/O psychology research, what concerns does this raise?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Organizational Psychology

82-4 What is the role of organizational psychologists?

Successfully recruiting, hiring, training, and appraising workers matters, but so does employee motivation and morale. Organizational psychologists assist with efforts to motivate and engage employees.

Satisfaction and Engagement at Work

MLive/Advance/Barcroft Media

An engaged employee Mohamed Mamow, left, was joined by his employer in saying the Pledge of Allegiance as he became a U.S. citizen. Mamow and his wife met in a Somali refugee camp and have five children, whom he has supported by working as a machine operator. Mindful of his responsibility—“I don’t like to lose my job. I have a responsibility for my children and my family”—he would arrive for work a half hour early and tend to every detail on his shift. “He is an extremely hard-working employee,” noted his employer, and “a reminder to all of us that we are really blessed” (Roelofs, 2010).

I/O psychologists have found that satisfaction with work, and with work-life balance, feeds overall satisfaction with life (Bowling et al., 2010). Married men and women who have supportive spouses often enjoy a healthy balance between work and home life, with success in both arenas (Solomon & Jackson, 2014). Moreover, as health psychologists tell us (and as we saw in Module 29), lower job stress, sometimes supported by telecommuting, feeds better health (Allen et al., 2015).

Satisfied employees also contribute to successful organizations. Positive moods at work enhance creativity, persistence, and helpfulness (Ford et al., 2011; Jeffrey et al., 2014; Shockley et al., 2012). Are engaged, happy workers also less often absent? Less likely to quit? Less prone to theft? More punctual? More productive? Statistical digests of prior research have found a modest positive correlation between individual job satisfaction and performance (Judge et al., 2001; Ng et al., 2009; Parker et al., 2003). In one analysis of 4500 employees at 42 British manufacturing companies, the most productive workers were those who found their work environment satisfying (Patterson et al., 2004).

Some organizations seem to have a knack for cultivating more engaged and productive employees. In the United States, *Fortune's* "100 Best Companies to Work For" have also produced markedly higher-than-average returns for their investors (Fulmer et al., 2003). And consider a study of more than 198,000 employees in nearly 8000 business units of 36 large companies (including some 1100 bank branches, 1200 stores, and 4200 teams or departments). James Harter, Frank Schmidt, and Theodore Hayes (2002) explored correlations between various measures of organizational success and *employee engagement*—the extent of workers' involvement, enthusiasm, and identification with their organizations (**Table 82.2**). They found that engaged workers (compared with disengaged workers who are just putting in their time) knew what was expected of them, had what they needed to do their work, felt fulfilled in their work, had regular opportunities to do what they do best, perceived that they were part of something significant, and had opportunities to learn and develop. They also found that business units with engaged employees had more loyal customers, lower turnover rates, higher productivity, and greater profits.

TABLE 82.2 Three Types of Employees

Engaged: working with passion and feeling a profound connection to their company or organization.
Not engaged: putting in the time but investing little passion or energy in their work.
Actively disengaged: unhappy workers undermining what their colleagues accomplish.

Information from Gallup via Crabtree, 2005.

Courtesy of New Lanark Trust

Doing well while doing good—"The Great Experiment" At the end of the 1700s, the New Lanark, Scotland, cotton mill had more than 1000 workers. Many were children drawn from Glasgow's poorhouses. They worked 13-hour days and lived in grim conditions.

On a visit to Glasgow, Welsh-born Robert Owen—an idealistic young cotton-mill manager—chanced to meet and marry the mill owner's daughter. Owen and some partners purchased the mill and on the first day of the 1800s began what he said was "the most important experiment for the happiness of the human race that had yet been instituted at any time in any part of the world" (Owen, 1814). The exploitation of child and adult labor was, he observed, producing unhappy and inefficient workers. Owen showed *transformational leadership* when he undertook numerous innovations: a nursery for preschool children, education for older children (with encouragement rather than corporal punishment), Sundays off, health care, paid sick days, unemployment pay for days when the mill could not operate, and a company store selling goods at reduced prices. He also innovated a goals- and worker-assessment program that included detailed records of daily productivity and costs but with "no beating, no abusive language."

The ensuing commercial success fueled a humanitarian reform movement. By 1816, with decades of profitability still ahead, Owen believed he had demonstrated "that society may be formed so as to exist without crime, without poverty, with health greatly improved, with little if any misery, and with intelligence and happiness increased a hundredfold." Although his utopian vision

> has not been fulfilled, Owen's great experiment laid the groundwork for employment practices that have today become accepted in much of the world.

But what causal arrows explain this correlation between business success and employee morale and engagement? Does success boost morale, or does high morale boost success? In a follow-up longitudinal study of 142,000 workers, researchers found that, over time, employee attitudes predicted future business success (more than the other way around) (Harter et al., 2010). Many other studies confirm that happy workers tend to be good workers (Ford et al., 2011; Seibert et al., 2011; Shockley et al., 2012). One analysis compared companies with top-quartile versus below-average employee engagement levels. Over a three-year period, earnings grew 2.6 times faster for the companies with highly engaged workers (Ott, 2007). It pays to have employees engaged.

Effective Leadership

82-5 How can leaders be most effective?

Great managers support employees' well-being, articulate goals clearly, and lead in ways that suit the situation and consider the cultural context.

Setting Specific, Challenging Goals

Measurable objectives, such as "finish gathering the history paper information by Friday," focus our attention and stimulate us to persist and to be creative. Goals motivate achievement, especially when combined with progress reports (Harkin et al., 2016). For many people, a landmark in time—a special birthday, the new year or new school term, graduation, a new job—spurs personal goal setting (Dai et al., 2014). Action plans that break large goals into smaller steps (subgoals) and that specify "implementation intentions"—when, where, and how to achieve those steps—increase the chances of completing a project on time (Fishbach et al., 2006; Gollwitzer & Sheeran, 2006). Through a task's ups and downs, we best sustain our mood and motivation when we focus on immediate goals (such as daily study) rather than distant goals (such as a class grade).

Better to have our nose to the grindstone than our eye on the ultimate prize (Houser-Marko & Sheldon, 2008).

> “ *The only place success comes before work is in the dictionary.* ”
>
> *Former Green Bay Packers football coach Vince Lombardi*

Thus, before beginning each new edition of this book, our author-editor-staff team *manages by objectives*—we agree on target dates for the completion and editing of each unit draft. If we focus on achieving each of these short-term goals, the prize—an on-time book—takes care of itself. So, to motivate high productivity, effective leaders work with people to define explicit goals, subgoals, and implementation plans, and then provide feedback on progress.

> “ *Good leaders don’t ask more than their constituents can give, but they often ask —and get—more than their constituents intended to give or thought it was possible to give.* ”
>
> *John W. Gardner,* Excellence, *1984*

Choosing an Appropriate Leadership Style

Effective leaders of laboratory groups, work teams, and large corporations often exude *charisma* (Goethals & Allison, 2014; House & Singh, 1987; Shamir et al., 1993). People with charisma have the ability to motivate people to cooperate toward a common goal (Grabo & van Vugt, 2016). Although charismatic leaders can inspire, **leadership**—the ability to motivate and influence people to enable their group’s success—varies, depending both on the leader and the situation. In some situations (think of a commander leading troops into battle), a *directive* style may be needed (Fiedler, 1981). In other situations—developing a comedy show, for example—a leader might get better results using a *democratic* style that welcomes team member creativity.

leadership
an individual’s ability to motivate and influence others to contribute to their group’s success.

Leaders differ in the personal qualities they bring to the job. Some excel at **task leadership**—by setting standards, organizing work, and focusing attention on goals. To keep the group centered on its mission, task leaders typically use a directive style, which can work well if the leader gives good directions (Fiedler, 1987).

task leadership
goal-oriented leadership that sets standards, organizes work, and focuses attention on goals.

Other managers excel at **social leadership**. They explain decisions, help group members solve their conflicts, and build teams that work well together (Evans & Dion, 1991; Pfaff et al., 2013). Social leaders, many of whom are women, often have a democratic style. They share authority and welcome team members’ opinions. Social leadership and team-building increases morale and productivity (Shuffler et al., 2011, 2013). We usually feel more satisfied and motivated, and perform better, when we can participate in decision making (Cawley et al., 1998; Pereira & Osburn, 2007). Moreover, when members are sensitive to one another and participate equally, groups solve problems with greater “collective intelligence” (Woolley et al., 2010).

social leadership
group-oriented leadership that builds teamwork, mediates conflict, and offers support.

In one study of 50 Dutch companies, the firms with the highest morale had chief executives who most inspired their colleagues "to transcend their own self-interests for the sake of the collective" (de Hoogh et al., 2004). *Transformational leadership* of this kind motivates others to identify with and commit themselves to the group's mission. Transformational leaders, many of whom are natural extraverts, articulate high standards, inspire people to share their vision, and offer personal attention (Bono & Judge, 2004). The frequent result is more engaged, trusting, and effective workers (Turner et al., 2002). Women more than men tend to exhibit transformational leadership qualities. Alice Eagly (2007, 2013) believes this helps explain why companies with female top managers have tended to enjoy superior financial results, even after controlling for such variables as company size.

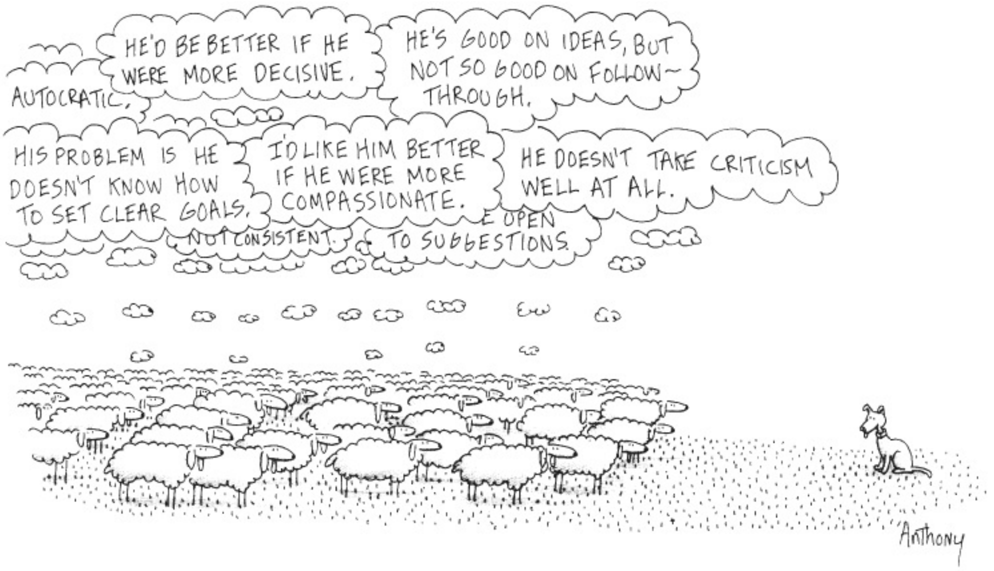
Scott Eklund/AP Images

The power of positive coaching Football coach Pete Carroll, who led the University of Southern California to two national championships and the Seattle Seahawks to a Super Bowl championship, has combined positive enthusiasm and fun workouts with "a commitment to a nurturing environment that allows people to be themselves while still being accountable to the team" (Trotter, 2014). "It shows you can win with positivity," noted Seahawks star defensive player Richard Sherman. "It's literally all positive reinforcement," said teammate Jimmy Graham (Belson, 2015).

Studies in India, Taiwan, and Iran suggest that effective managers—whether in coal mines, banks, or government offices—often exhibit a high degree of *both* task and social leadership (Smith & Tayeb, 1989). As achievement-minded people, effective managers care about how well work is done, yet they are sensitive to their subordinates' needs. Workers in family-friendly organizations that offer flexible-time hours report feeling greater job satisfaction and loyalty to their employers (Butts et al., 2013; Roehling et al., 2001). Over time, U.S. senators who practice common virtues (humility, wisdom, courage) become more influential in leadership roles than do those who practice manipulation and intimidation (ten Brinke et al., 2016). Social virtues work.

POSITIVE REINFORCEMENT Effective leadership often builds on a basic principle of *operant conditioning:* To teach a behavior, catch a person doing something right and reinforce it. It sounds simple, but many managers are like parents who, when a child brings home a near-perfect school report card, focus on the one low grade in a troublesome biology class and ignore the rest. "Sixty-five percent of Americans received NO praise or recognition in the workplace last year," reported the Gallup Organization (2004).

FULFILLING THE NEED TO BELONG A work environment that satisfies employees' need to belong is energizing. Employees who enjoy high-quality colleague relationships engage their work with more vigor (Carmeli et al., 2009). Gallup researchers have asked more than 15 million employees worldwide if they have a "best friend at work." The 30 percent who do "are *seven times* as likely to be engaged in their jobs" as those who don't, report Tom Rath and James Harter (2010). And, as we noted earlier, positive, engaged employees are a mark of thriving organizations.



HE'D BE BETTER IF HE WERE MORE DECISIVE.
HE'S GOOD ON IDEAS, BUT NOT SO GOOD ON FOLLOW-THROUGH.
AUTOCRATIC.
HIS PROBLEM IS HE DOESN'T KNOW HOW TO SET CLEAR GOALS.
I'D LIKE HIM BETTER IF HE WERE MORE COMPASSIONATE.
HE DOESN'T TAKE CRITICISM WELL AT ALL.
NOT CONSISTENT.
OPEN TO SUGGESTIONS.
Anthony

PARTICIPATIVE MANAGEMENT Employee participation in decision making is common in Sweden, Japan, the United States, and elsewhere (Cawley et al., 1998; Sundstrom et al., 1990). Workers given a chance to voice their opinion and be part of the decision-making process have responded more positively to the final decision (van den Bos & Spruijt, 2002). They also feel more empowered and are likely, therefore, to be more creative and committed (Hennessey & Amabile, 2010; Seibert et al., 2011).

The ultimate in employee participation is the employee-owned company. One such company in my [DM's] town is the Fleetwood Group—a thriving 165-employee manufacturer of educational furniture and wireless electronic clickers. Every employee owns part of the company, and as a group they own 100 percent. The more years employees work, the more they own, yet no one owns more than 5 percent. Like every corporate president, Fleetwood's president works for his stockholders—who also just happen to be his employees.

As a company that endorses faith-inspired *servant leadership* and "respect and care for each team member-owner," Fleetwood is free to place people above profits. Thus, when orders lagged during a recession, the employee-owners decided that job security meant more to them than profits. So the company paid otherwise idle workers to do community service, such as answering phones at nonprofit agencies and building

Habitat for Humanity houses. Employee ownership attracts and retains talented people, which for Fleetwood has meant company success.

Cultural Influences on Leadership Styles

82-6 What cultural influences need to be considered when choosing an effective leadership style?

Industrial-organizational psychology sprang from North American roots. So, how well do its leadership principles apply to cultures worldwide?

Investigators worldwide have undertaken Project GLOBE (Global Leadership and Organizational Behavior Effectiveness), to study cultural variations in leadership expectations (House et al., 2001). Some cultures, for example, encourage collective sharing of resources and rewards; others are more individualist. Some cultures minimize and others accentuate traditional gender roles. Some cultures prioritize being friendly, caring, and kind, and others encourage aggressiveness. The program’s first research phase studied 17,300 leaders of 950 organizations in 61 countries (Brodbeck et al., 2008; Dorfman et al., 2012). One finding: Leaders who fulfill expectations, such as by being directive in some cultures or participative in others, tend to be successful. Cultures shape leadership and what makes for leadership success.

Nevertheless, some leader behaviors are universally effective. From its massive study of nearly 50,000 business units in 45 countries, the Gallup Organization observed that thriving companies tend to focus on identifying and enhancing employee *strengths* (rather than punishing their deficiencies). Doing so predicts increased employee engagement, customer satisfaction, and profitability (Rigoni & Asplund, 2016a,b). “Strengths-based” leadership pays dividends. By caring about their employees and engaging and affirming their strengths, such leaders support happier, more creative, more productive workers with less absenteeism and turnover (Amabile & Kramer, 2011; De Neve et al., 2013). Moreover, the same principles affect college student satisfaction, retention, and future success (Larkin et al., 2013; Ray & Kafka, 2014). Students who feel supported by caring friends and mentors, and engaged in their campus life, tend to persist and ultimately succeed during school and after graduation.

* * *

We have considered *personnel psychology* (the I/O psychology subfield that focuses on training job seekers and assisting with employee selection, placement, appraisal, and development). And we have considered *organizational psychology* (the I/O psychology subfield that focuses on worker satisfaction and productivity, and on organizational change). Finally, we turn to *human factors psychology*, which explores the human-machine interface.

Ask Yourself

- How might you use what you've learned about effective goal-setting to achieve more in your own life?

Test Yourself

- What are the two basic types of leadership, and how do the most effective managers employ these leadership strategies?
- What characteristics are important for transformational leaders?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Human Factors Psychology

82-7 How do human factors psychologists work to create user-friendly machines and work settings?

Designs sometimes neglect the human factor. Cognitive scientist Donald Norman (2001) bemoaned the complexity of assembling his new HDTV, related components, and seven remotes into a usable home theater system: “I was VP of Advanced Technology at Apple. I can program dozens of computers in dozens of languages. I understand television, really, I do. . . . It doesn’t matter: I am overwhelmed.”

Human factors psychologists work with designers and engineers to tailor appliances, machines, and work settings to our natural perceptions and inclinations. Bank ATM machines are internally more complex than remote controls ever were, yet thanks to human factors engineering, ATMs are easier to operate. Digital recorders have solved the TV recording problem with a simple select-and-click menu system (“record that one”). Apple similarly engineered easy usability with the iPhone and iPad. Handheld and wearable technologies are increasingly making use of *haptic* (touch-based) feedback—opening a phone with a thumbprint, sharing your heartbeat via a smartwatch, or having GPS directional instructions (“turn left” arrow) “drawn” on your skin with other wrist-worn devices.

Norman hosts a website (jnd.org) that illustrates good designs that fit people (**Figure 82.3**). Human factors psychologists also help design efficient environments. An ideal kitchen layout, researchers have found, puts needed items close to their usage point and near eye level. It locates work areas to enable doing tasks in order, such as placing the refrigerator, stove, and sink in a triangle. It creates counters that enable hands to work at or slightly below elbow height (Boehm-Davis, 2005).

Figure 82.3 Designing products that fit people

Human factors expert Donald Norman offers these and other examples of effectively designed products. The Ride On Carry On foldable chair attachment, “designed by a flight attendant mom,” enables a small suitcase to double as a stroller. The Oxo measuring cup allows the user to see the quantity from above.

Understanding human factors can help prevent accidents. By studying the human factor in driving accidents, psychologists seek to devise ways to reduce the distractions, fatigue, and inattention that contribute to 1.25 million annual worldwide traffic fatalities (WHO, 2016). At least two-thirds of commercial air accidents have been caused by human error (Shappell et al., 2007). After beginning commercial flights in the 1960s, the Boeing 727 was involved in several landing accidents caused by pilot error. Psychologist Conrad Kraft (1978) noted a common setting for these accidents: All took place at night, and all involved landing short of the runway after crossing a dark stretch of water or unilluminated ground. Kraft reasoned that, on rising terrain, city lights beyond the runway would project a larger retinal image, making the ground seem farther away than it was. By re-creating these conditions in flight simulations, Kraft discovered that pilots were deceived into thinking they were flying higher than their actual altitudes (**Figure 82.4**). Aided by Kraft’s finding, the airlines began requiring the co-pilot to monitor the altimeter—calling out altitudes during the descent—and the accidents diminished.

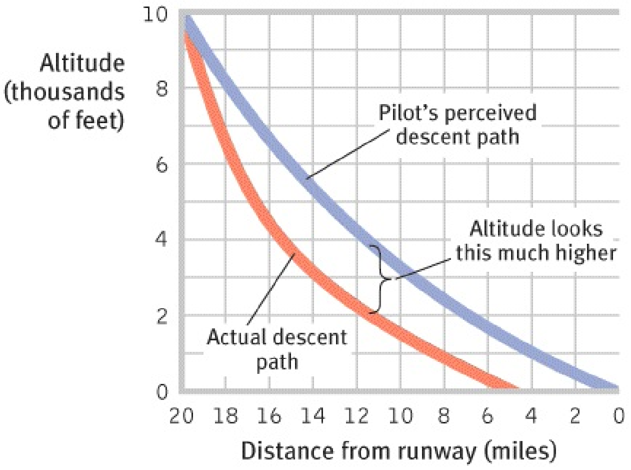

Figure 82.4

Data from Kraft, 1978.

Figure 82.4 The human factor in accidents

Lacking distance cues when approaching a runway from over a dark surface, pilots simulating a night landing tended to fly too low.

Human factors psychologists can also help us to function in other settings. Consider the available assistive listening technologies in various theaters, auditoriums, and places of worship. One technology, commonly available in the United States, requires a headset attached to a pocket-sized receiver. The well-meaning people who provide these systems correctly understand that the technology puts sound directly into the user’s ears. Alas, few people with hearing loss elect the hassle and embarrassment of locating, requesting, wearing, and returning a conspicuous headset. Most such units therefore sit in closets. Britain, the Scandinavian countries, Australia, and now many parts of the United States have instead installed *loop systems* (see hearingloop.org) that broadcast customized sound directly through a person’s own hearing aid. When suitably equipped, a hearing aid can be transformed by a discreet touch of a switch into a customized in-the-ear speaker. When offered convenient, inconspicuous, personalized sound, many more people elect to use assistive listening.

Designs that enable safe, easy, and effective interactions between people and technology often seem obvious after the fact. Why, then, aren't they more common? Technology developers, like all of us, sometimes mistakenly assume that others share their expertise—that what's clear to them will similarly be clear to others (Camerer et al., 1989; Nickerson, 1999). When people rap their knuckles on a table to convey a familiar tune (try this with a friend), they often expect their listener to recognize it. But for the listener, this is a near-impossible task (Newton, 1991). When you know a thing, it's hard to mentally simulate what it's like not to know, and that is called the *curse of knowledge.*

Steven Day/AP Images

The human factor in safe landings Advanced cockpit design and rehearsed emergency procedures aided pilot Chesley "Sully" Sullenberger, a U.S. Air Force Academy graduate who earned a Master's degree in industrial psychology. In 2009, Sullenberger's instantaneous decisions safely guided his disabled airplane onto New York City's Hudson River, where all 155 of the passengers and crew were safely evacuated.

> “*The better you know something, the less you remember about how hard it was to learn.*”
>
> *Psychologist Steven Pinker,* The Sense of Style, *2014*

The point to remember: Everyone benefits when designers and engineers tailor machines, technologies, and environments to fit human abilities and behaviors, when they user-test their work before production and distribution, and when they remain mindful of the curse of knowledge.

✓ Check Your Understanding

Ask Yourself

- What situations have you experienced (using new technology, visiting new or remodeled building spaces, taking various modes of transportation) where the design did not work well? What situations have you experienced in which planners did a particularly good job matching machines and physical environments to our abilities and expectations?

Test Yourself

- What is the *curse of knowledge*, and what does it have to do with the work of human factors psychologists?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 82 REVIEW

82-1 What is *flow*?

- *Flow* is a completely involved, focused state of consciousness with diminished awareness of self and time. It results from fully engaging one's skills.

82-2 What are three key areas of study related to industrial-organizational psychology?

- I/O psychology's three subfields are *personnel, organizational,* and *human factors* psychology.

82-3 How do personnel psychologists facilitate job seeking, employee selection, work placement, and performance appraisal?

- Personnel psychologists work with job seekers to improve their searching and self-presentation skills, and with organizations to devise selection methods for new employees, recruit and evaluate applicants, design and evaluate training programs, identify people's strengths, analyze job content, and appraise individual and organizational performance.
- Unstructured interviews foster the interviewer illusion; *structured interviews* pinpoint job-relevant strengths and are better predictors of performance.
- Checklists, graphic rating scales, and behavior rating scales are useful performance appraisal methods.

82-4 What is the role of organizational psychologists?

- Organizational psychologists examine influences on worker satisfaction and productivity and facilitate organizational change. Employee satisfaction and engagement tend to correlate with organizational success.

82-5 How can leaders be most effective?

- Effective leaders set specific challenging goals and choose an appropriate leadership style. Leadership style may be goal-oriented *(task leadership)*, group-oriented *(social leadership)*, or some combination of the two.

82-6 What cultural influences need to be considered when choosing an effective leadership style?

- Leaders who fulfill their culture’s expectations—by promoting individualism or collectivism, kindness or aggressiveness, or the accentuating or downplaying of gender roles—tend to be successful.
- Other leader behaviors—such as supporting employees by focusing on their strengths—are universally effective.

82-7 How do human factors psychologists work to create user-friendly machines and work settings?

- Human factors psychologists contribute to human safety and improved design by encouraging developers and designers to consider human perceptual abilities, to avoid the curse of knowledge, and to test users to reveal perception-based problems.

Multiple-Choice Questions

1. Carla is reading a gripping novel and loses track of time, making her late for practice. Carla may have been experiencing

a. flow.
b. I/O psychology.
c. self-efficacy.

d. performance appraisal.
e. the curse of knowledge.

2. Job-seekers at a company are screened by different interviewers, but each is asked the same questions. The company is making use of

a. flow.
b. structured interviews.
c. employee engagement.
d. unstructured interviews.
e. human factors psychology.

3. The overall goal of 360-degree feedback is

a. self-rating.
b. achieving flow.
c. performance appraisal.
d. employee selection.
e. achieving transformational leadership.

Practice FRQ

1. Compare and contrast the type of work done by the following psychologists:

- Organizational
- Human factors
- Personnel

(3 points)

Module **83 Animal Thinking and Language**

LEARNING TARGETS

- **83-1 Discuss what we know about thinking in other species.**
- **83-2 Discuss what we know about other species' capacity for language.**

Do Other Species Share Our Cognitive Skills?

83-1 What do we know about thinking in other species?

Other animals are surprisingly smart (de Waal, 2016) (**Figure 83.1**). In her 1908 book, *The Animal Mind*, pioneering psychologist Margaret Floy Washburn argued that animal consciousness and intelligence can be inferred from their behavior. In 2012, neuroscientists convening at the University of Cambridge added that animal consciousness can also be inferred from their brains: “Nonhuman animals, including all mammals and birds,” possess the neural networks “that generate consciousness” (Low, 2012). Consider, then, what animal brains can do. Module 34 described animals displaying insight, but here are some other animal tricks.

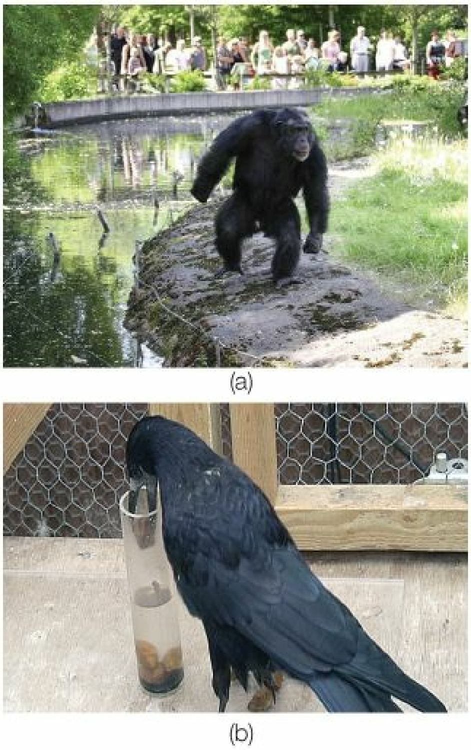

Figure 83.1
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
(a) Neurology/PA/AP Photo; (b) Chris Bird & Nathan Emery

Figure 83.1 Animal talents

(a) One male chimpanzee in Sweden’s Furuvik Zoo was observed every morning collecting stones into a neat little pile, which later in the day he used as ammunition to pelt visitors (Osvath & Karvonen, 2012). (b) Crows studied by Christopher Bird and Nathan Emery (2009) quickly learned to raise the water level in a tube and nab a floating worm by dropping in stones. Other crows have used twigs to probe for insects, and bent strips of metal to reach food.

Using Concepts and Numbers

By touching screens in quest of a food reward, black bears have learned to sort pictures into animal and nonanimal categories, or concepts (Vonk et al., 2012). Chimpanzees, gorillas, and monkeys also form concepts, such as *cat* and *dog*. After monkeys have learned these concepts, certain frontal lobe neurons in their brain fire in response to new “cat-like” images, others to new “dog-like” images (Freedman et al., 2001). Even pigeons—mere birdbrains—can sort objects (pictures of cars, cats, chairs, flowers) into categories. Shown a picture of a never-before-seen chair, pigeons will reliably peck a key that represents *chairs* (Wasserman, 1995).

Transmitting Culture

Like humans, other species invent behaviors and transmit cultural patterns to their observing peers and offspring (Boesch-Achermann & Boesch, 1993). Forest-dwelling chimpanzees select different tools for different purposes—a heavy stick for making holes, a light, flexible stick for fishing for termites, a pointed stick for roasting marshmallows. (Just kidding: They don’t roast marshmallows, but they have surprised us with their sophisticated tool use [Sanz et al., 2004]). Researchers have found at least 39 local customs related to chimpanzee tool use, grooming, and courtship (Claidière & Whiten, 2012; Whiten & Boesch, 2001). One group may slurp termites directly from a stick, another group may pluck them off individually. One group may break nuts with a stone hammer, while their neighbors use a wooden hammer. One chimpanzee discovered that tree moss could absorb water for drinking from a waterhole, and within six days seven other observant chimpanzees began doing the same (Hobaiter et al., 2014). These transmitted behaviors, along with differing communication and hunting styles, are the chimpanzee version of cultural diversity.

Several experiments have brought chimpanzee and baboon cultural transmission into the laboratory (Claidière et al., 2014; Horner et al., 2006). If Chimpanzee A obtains food either by sliding or by lifting a door, Chimpanzee B will then typically do the same to get food. And so will Chimpanzee C after observing Chimpanzee B. Across a chain of six animals, chimpanzees see, and chimpanzees do.

Other Cognitive Skills

Mike Lovett

Animal cognition in action Until his death in 2007, Alex, an African Grey parrot, categorized and named objects (Pepperberg, 2009, 2012, 2013). Among his jaw-dropping numerical skills was the ability to comprehend numbers up to 8. He could speak the number of objects. He could add two small clusters of objects and announce the sum. He could indicate which of two numbers was greater. And he gave correct answers when shown various groups of objects. Asked, for example, “What color four?” (meaning “What’s the color of the objects of which there are four?”), he could speak the answer.

A baboon in an 80-member troop can distinguish every other member’s voice (Jolly, 2007). Great apes, dolphins, and elephants recognize themselves in a mirror, demonstrating self-awareness. Dolphins form coalitions, cooperatively hunt, and learn tool use from one another (Bearzi & Stanford, 2010). In Shark Bay, Western Australia, a small group of dolphins learned to use marine sponges as protective nose guards when probing the sea floor for fish (Krützen et al., 2005). Elephants also display their abilities to learn, remember, discriminate smells, empathize, cooperate, teach, and spontaneously use tools (Byrne et al., 2009).

Chimpanzees show altruism, cooperation, and group aggression. Like humans, they will purposefully kill their neighbor to gain land, and they grieve over dead relatives (Anderson et al., 2010; Biro et al., 2010; Mitani et al., 2010).

* * *

There is no question that other species display many remarkable cognitive skills. But one big question remains: Do they, like humans, exhibit language?

Do Other Species Have Language?

83-2 What do we know about other species' capacity for language?

Humans have long and proudly proclaimed that language sets us above all other animals. "When we study human language," asserted linguist Noam Chomsky (1972), "we are approaching what some might call the 'human essence,' the qualities of mind that are, so far as we know, unique [to humans]." Let's see if research on animal language supports claims that humans, alone, have language.

Some animals display basic language processing. Pigeons can learn the difference between words and nonwords, but they could never read this book (Scarf et al., 2016). Other animals show impressive comprehension and communication. Various monkey species sound different alarm cries for different predators, such as a barking call for a leopard, a cough for an eagle, and a chuttering for a snake. Hearing the leopard alarm, vervets climb the nearest tree. Hearing the eagle alarm, they rush into the bushes. Hearing the snake chutter, they stand up and scan the ground (Byrne, 1991; Clarke et al., 2015; Coye et al., 2015). To indicate such things as a type of threat—an eagle, a leopard, a falling tree, a neighboring group—monkeys will combine 6 different calls into a 25-call sequence (Balter, 2010). But are such communications language?

Jim Cummins/Getty Images

Talking hands Human language appears to have evolved from gestured communications (Corballis, 2002, 2003; Pollick & de Waal, 2007). Even today, gestures are naturally associated with spontaneous speech, and similarly so for blind and sighted speakers of a given language (Özçaliskan et al., 2016). Both gesture and speech communicate, and when they convey the same rather than different information (as they do in baseball's sign language), we humans understand faster and more accurately (Hostetter, 2011; Kelly et al., 2010). Outfielder William Hoy, the first deaf player to join the major leagues (1892), reportedly helped invent hand signals for “Strike!” “Safe!” (shown here) and “Yerr out!” (Pollard, 1992). Referees in all sports now use invented signs, and fans are fluent in sports sign language.

In the late 1960s, psychologists Allen Gardner and Beatrix Gardner (1969) aroused enormous scientific and public interest with their work with Washoe, a young chimpanzee. Building on chimpanzees’ natural tendencies for gestured communication, they taught Washoe sign language. After four years, Washoe could use 132 signs; by her life’s end in 2007, she was using 250 signs (Metzler, 2011; Sanz et al., 1998).

During the 1970s, more and more reports came in. Some chimpanzees were stringing signs together to form sentences. Washoe, for example, signed “You me go out, please.” Some word combinations seemed creative—saying *water bird* for “swan” or *apple-which-is-orange* for “orange” (Patterson, 1978; Rumbaugh, 1977).

But by the late 1970s, other psychologists were growing skeptical. Were the chimps language champs or were the researchers chumps? Consider, said the skeptics:

- Ape vocabularies and sentences are simple, rather like those of a 2-year-old child. And apes gain their limited vocabularies only with great difficulty (Wynne, 2004, 2008). Speaking or signing children can easily soak up dozens of new words each week, and 60,000 by adulthood.
- Chimpanzees can make signs or push buttons in sequence to get a reward. But pigeons, too, can peck a sequence of keys to get grain (Straub et al., 1979). The apes’ signing might be nothing more than aping their trainers’ signs and learning that certain arm movements produce rewards (Terrace, 1979).
- When information is unclear, we are prone to *perceptual set*—a tendency to see what we want or expect to see (Module 17). Interpreting chimpanzee signs as language may have been little more than the trainers’ wishful thinking (Terrace, 1979). When Washoe signed *water bird*, she may have been separately naming *water* and *bird*.

- “Give orange me give eat orange me eat orange . . .” is a far cry from the exquisite syntax of a 3-year-old (Anderson, 2004; Pinker, 1995). Rules of syntax in human language govern the order of words in sentences, so to a child, “You tickle” and “Tickle you” communicate different ideas. A chimpanzee, lacking these rules of syntax, might use the same sequence of signs for both phrases.

Susanne Baus/AFP/Getty Images/Newscom

Comprehending canine Border collie Rico had a vocabulary of 200 human words. If asked to retrieve a toy with a name he had never heard, Rico would pick out a new toy from a group of familiar items (Kaminski et al., 2004). Hearing that name for the second time four weeks later, Rico more often than not would retrieve the same toy. Another border collie, Chaser, has set an animal record by learning more than 1000 object names (Pilley, 2013). Like a 3-year-old child, she can also categorize them by function and shape. She can “fetch a ball” or “fetch a doll.”

Controversy can stimulate progress, and in this case, it triggered more evidence of chimpanzees’ abilities to think and communicate. One surprising finding was that Washoe trained her adopted son Loulis to use the signs she had learned. After her second infant died, Washoe became withdrawn when told, “Baby dead, baby gone, baby finished.” Two weeks later, researcher-caretaker Roger Fouts (1992, 1997) signed better news: “I have baby for you.” Washoe reacted with instant excitement. Hair on end, she swaggered and panted while signing over and again, “Baby, my baby.” It took several hours for the foster mom and infant to warm to each other, but then Washoe broke the ice by signing, “Come baby” and cuddling Loulis. Without human assistance, Loulis eventually picked up 68 signs, simply by observing Washoe and three other language-trained chimps signing together.

Even more stunning was a later report: Kanzi, a bonobo with a reported 384-word vocabulary, could understand syntax in spoken English (Savage-Rumbaugh et al., 1993, 2009). Kanzi, who appears to have the receptive language ability of a human 2-year-old, has responded appropriately when asked, “Can you show me the light?” and “Can you bring me the [flash]light?” and “Can you turn the light on?” Given stuffed animals and asked—for the first time—to “make the dog bite the snake,” he put the snake to the dog’s mouth.

Paul Fusco/Magnum

But is this language? Chimpanzees’ ability to express themselves in American Sign Language (ASL) raises questions about the very nature of language. Here, the trainer is asking, “What is this?” The sign in response is “Baby.” Does the response constitute language?

So, how should we interpret such studies? Are humans the only language-using species? If by *language* we mean an ability to communicate through a meaningful sequence of symbols, then apes are indeed capable of language. But if we mean a verbal or signed expression of complex grammar, most psychologists would now agree that humans alone possess language. Moreover, 2½-year-old children display some cognitive abilities, such as following an actor’s gaze to a target, that are unmatched even by chimpanzees (Herrmann et al., 2010). Humans, alone, also have a version of a gene *(FOXP2)* that helps enable the lip, tongue, and vocal cord movements of human speech (Lieberman, 2013). Humans with a mutated form of this gene have difficulty speaking words.

One thing is certain: Studies of animal language and thinking have moved psychologists toward a greater appreciation of other species’ remarkable abilities (Friend, 2004; Rumbaugh & Washburn, 2003; Wilson et al., 2015). In the past, many psychologists doubted that other species could plan, form concepts, count, use tools, or show compassion (Thorpe, 1974). Today, thanks to animal researchers, we know better. Other species exhibit insight, show family loyalty, communicate with and care for one another, and transmit cultural patterns across generations. Working out what this means for the moral rights of other animals is an unfinished task.

✓ Check Your Understanding

Ask Yourself

- Can you think of a time when you felt an animal was communicating with you? How might you put such intuition to a test?

Test Yourself

- If your dog barks at a stranger at the door, does this qualify as language? What if the dog yips in a telltale way to let you know she needs to go out?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 83 REVIEW

83-1 What do we know about thinking in other species?

- Researchers make inferences about other species' consciousness and intelligence based on behavior. The main focus of such research has been the great apes, but other species have also been studied.
- Evidence to date shows that other species can use concepts, numbers, and tools, and they can transmit learning from one generation to the next (cultural transmission). They also show insight, self-awareness, altruism, cooperation, and grief.

83-2 What do we know about other species' capacity for language?

- A number of great apes (mostly chimpanzees) have learned to communicate with humans by signing or by pushing buttons, have developed vocabularies of nearly 400 words, have communicated by stringing these words together, have taught their skills to younger animals, and have shown some understanding of syntax.
- While only humans communicate in complex sentences, primates' and other animals' impressive abilities to think and communicate challenge humans to consider what this means about the moral rights of other species.

Multiple-Choice Questions

1. Which of the following is an example of an animal using concepts?

a. A parrot identifies the number and color of objects.
b. A dog identifies the scent of her owner.
c. A parrot learns to say phrases.
d. A dog fetches a thrown stick.
e. A parrot quiets when the cover is put over his cage at night.

2. Researchers have found that groups of animals will share certain customs, such as ways of using tools. This is an example of

a. self-awareness.
b. altruism.
c. cultural transmission.
d. insight.
e. language use.

Practice FRQ

1. Provide a specific example from the text of animal thinking, animal tool use, and animal language.

Appendix A: Practice AP®-Style Exam

1. The Big Five model suggests that people can be rated along the dimensions of conscientiousness, agreeableness, neuroticism, openness, and extraversion. This theory is best associated with which of the following?

a. Trait theory
b. Psychodynamic theory
c. The cognitive approach
d. The humanistic approach
e. The biological approach

2. Warren has a bacterial infection that has affected the ability of the rods in his eyes to function correctly. This should have the greatest impact on which of the following?

a. Visual clarity
b. Peripheral vision
c. Color vision
d. Hearing high-frequency sounds
e. Hearing low-frequency sounds

3. Seeking out information that supports our previously held beliefs, while discounting information that questions those beliefs, is an obstacle to problem solving known as

a. functional fixedness.

b. a logical fallacy.
c. overconfidence.
d. mental set.
e. confirmation bias.

4. Joe is taking a new job on the night shift next week. His supervisors have informed him that initially he may have some problems with his level of alertness and his memory as he adjusts to his new schedule. Joe's supervisors are sharing with Joe their knowledge of

a. circadian rhythms.
b. REM sleep.
c. sleep spindles.
d. the social clock.
e. NREM sleep.

5. A researcher who is trying to determine how social-cultural changes might be correlated with the incidence of bipolar disorder would be most interested in which of the following?

a. The brain changes in a person with bipolar disorder as measured by a PET scan
b. Scientific measures of the heritability of the disorder
c. The correlation between rates of poverty and cases of the disorder
d. Neurotransmitter levels in patients diagnosed with the disorder
e. The number of close biological relatives who also suffer from bipolar disorder

6. Zeina cocked her head to the side immediately when she heard the fire truck's siren. Turning her head enabled each ear to detect a slightly different intensity of sound, thus enabling her to determine the siren's

a. timbre.
b. pitch.
c. frequency.
d. location.
e. tone.

7. A police officer questions a child who was an eyewitness to a crime. The officer is most likely to get accurate information if she:

a. first tells the child all about the crime the way she thinks it unfolded.
b. uses neutral, age-appropriate words and is the first to interview the child.
c. uses neutral, age-appropriate words and is the last to interview the child.
d. uses suggestive techniques to get the story from the child.
e. tells the child a story about a similar crime to get the child thinking about possibly similar details.

8. People diagnosed with OCD experience compulsions. Which of the following is a compulsion?

a. Renee persistently thinks about the possible death of her loved ones.
b. Eric frequently worries that there may be germs on his hands.
c. Brianna has an ongoing worry that she might have left the oven on at home.
d. Stefan often feels great anxiety if things are not in exact order in his room.
e. Tyrik flips the light switch on and off seven times every evening when he walks in the front door.

9. When a person performs a heroic act solely for public praise, she is on which developmental level according to Lawrence Kohlberg?

a. Preconventional
b. Postconventional
c. Conventional
d. Concrete operational
e. Formal operational

0. The bus driver was surprised when her first passenger asked her to turn the music down, because she thought the volume was fine. When the passenger said something, and the driver could barely hear the person, the driver realized the music was too loud. Which of the following statements best explains the driver’s initial indifference to the music volume?

a. The initial music volume was below her absolute threshold.
b. The driver had a decreased ability to determine the music’s pitch.
c. The just noticeable difference of the music was too great.
d. The driver had adapted to the initial volume of the music.
e. The driver was using bottom-up processing instead of top-down processing.

1. A rat jumps each time it sees a green light flash, because the green light has always appeared just before an electric shock. In classical conditioning, the initial learning of the connection between the light and the shock is referred to as

a. spontaneous recovery.
b. extinction.
c. generalization.
d. accommodation.
e. acquisition.

2. Which of the following examples is the best illustration of cognitive dissonance?

a. The cult member who admires the leader of his group and follows the leader without doubt
b. The teacher who reprimands a student who she feels could do much better academically
c. The soldier who receives orders from a superior to do something that violates his personal moral beliefs
d. The librarian who dreams of returning to graduate school to become a professor
e. The student who gives up trying to master calculus because it seems too hard

3. At their high school reunion, many attendees recalled exactly where they were 20 years before when they realized the school was on fire.

Strong memories of an emotionally significant moment are referred to as

a. flashbulb memories.
b. state-dependent memories.
c. short-term memories.
d. sensory memories.
e. critical period memories.

4. Of the following, for *which* pair are both used to reveal activity in a person’s brain?

a. CT scan and PET scan
b. X-ray and fMRI
c. fMRI and MRI
d. PET scan and fMRI
e. CT scan and MRI

5. A therapist who believes in giving patients positive reinforcement when they behave appropriately is most likely to use which of the following techniques?

a. Systematic desensitization
b. Token economy
c. Aversive conditioning
d. Transference
e. Exposure therapy

6. Phil complained to his doctor that the sleeping pill the doctor previously prescribed no longer was effective at the original dosage. To his doctor’s dismay, Phil confided that he had been taking more than the recommended amount of the drug to get the same effect. Phil’s increasing intake of the drug reflects the condition known as

a. withdrawal.
b. sensory overload.
c. tolerance.
d. catharsis.

e. REM rebound.

7. Students who have recently learned “correlation does not equal causation” should be most cautious of the findings in which news headline below?

a. “Coffee drinkers live longer, surveys say.”
b. “101-year-old man still healthy and happy.”
c. “Flu shots lower the risk of infection by 87 percent in lab studies.”
d. “Skim milk consumption tied to decreased neuron growth in studies of mice.”
e. “Observers note men less likely than women to wash their hands in public restrooms.”

8. The symptoms of schizophrenia can be categorized as positive or negative. Which of the following symptoms can be considered positive?

a. Hallucinations
b. Flat affect
c. Social withdrawal
d. Catatonia
e. Toneless vocal patterns

9. Mary Ainsworth designed the “strange situation” experiment in order to determine

a. how creative young children could be in novel environments.
b. whether children had developed a secure attachment to their mother.
c. if children were more motivated by social anxiety than by peer pressure.
d. if the parenting style of mothers affected their children’s temperament.
e. if early signs of imprinting in young children could be reversed.

0. A principal wants to avoid the vandalism and inappropriate behavior that occurred at last year’s Halloween dance. So, this year she decides to increase the lighting in the parking lots, ban students from wearing masks over their faces, and increase the number of video cameras near the gym. These ideas are most closely linked to the principle of

a. group polarization.
b. social facilitation.
c. superordinate goals.
d. deindividuation.
e. minority influence.

1. Longitudinal studies suggest that certain characteristics, such as reactivity and intensity, appear early in life and remain stable from childhood into adulthood. Psychologists use what term to refer to these aspects of personality?

a. Schema
b. Reflex
c. Temperament
d. Fixation
e. Sensory adaptation

2. One way to determine if infants can perceive a certain stimulus is to measure how long they gaze at the item before looking away. Psychologists use what term to refer to the concept that infants tend to decrease their rate of responding when a stimulus is repeated and no longer novel?

a. Sensory adaptation
b. Infantile amnesia
c. Perceptual set
d. Perceptual constancy
e. Habituation

3. An injury that leads to the loss of binocular vision would have the greatest impact on

a. visual acuity.
b. color perception.
c. peripheral vision.

d. depth perception.
e. selective attention.

4. The stage of sleep in which an EEG would detect the bursts of rhythmic activity known as sleep spindles is called

a. REM sleep.
b. NREM-1.
c. NREM-2.
d. NREM-3.
e. hypnagogic sleep.

5. Ulric’s doctor suggested that he consider moving to an area where there is greater sunlight or purchasing a light box that emits a bright light. Given these treatment options, Ulric’s doctor must have diagnosed Ulric with

a. attention-deficit/hyperactivity disorder.
b. a seasonal pattern for depressive disorders.
c. posttraumatic stress disorder.
d. antisocial personality disorder.
e. agoraphobia.

6. Damage to which of the following brain areas would create the most difficulty in interpreting feelings of heat and cold?

a. Motor cortex
b. Sensory cortex
c. Frontal lobe
d. Temporal lobe
e. Occipital lobe

7. A substance that interrupts neural transmission by fitting into a receptor site but not activating it, or by preventing another neurotransmitter from accessing the receptor site, is known as

a. an agonist.
b. an antagonist.

c. an endorphin.
d. a hormone.
e. the synaptic cleft.

8. Which of the following coefficients reflects the strongest correlation between two variables?

a. 0.42
b. –0.31
c. 0.74
d. –0.88
e. 0.86

9. After Donnie realized the “intruder” in his home was just his mother returning unexpectedly, his breathing began to slow down, his heart rate decreased, and his digestion began again. These changes were coordinated by the

a. limbic system.
b. parasympathetic nervous system.
c. sympathetic nervous system.
d. afferent neurons.
e. efferent neurons.

0. The oldest theory about human motivation, which focuses on unlearned, complex patterns of behavior present throughout a species, is known as

a. arousal theory.
b. drive-reduction theory.
c. instinct theory.
d. extrinsic motivation.
e. the hierarchy of needs.

1. Prefixes and suffixes are small groups of letters that when added to the beginning or ending of words alter the definition of those words. Prefixes and suffixes, then, are examples of

a. phonemes.
b. morphemes.
c. algorithms.
d. accommodation.
e. assimilation.

2. Which of the following most accurately describes a projective test?

a. A test designed to reveal a person's inner ability to do a task he or she has not tried before.
b. A test that shows a person's true preferences, based on responses to multiple-choice questions.
c. A test that indicates the level of indifference to pain that a person experiences.
d. A test created to see if one has an anxiety-inducing problem, but is instead claiming that others have that problem.
e. A test that prompts a person to reveal hidden conflicts by responding to ambiguous stimuli.

3. Mr. Winters is a trainer who encourages his clients to lose weight. Instead of simply rewarding them when their weight declines, he is rewarding them each time they behave in ways that would reduce weight—each time they exercise, decline high-calorie foods, or even take the stairs at work. Reinforcing each time one gets closer to a desired behavior is known as

a. conforming.
b. extinguishing.
c. social loafing.
d. shaping.
e. classical conditioning.

4. Often restaurants will require groups of eight or more to pay a tip of 18 percent. This is based on the belief that in larger parties, individuals will often leave a smaller tip because "someone else will pay more." These restaurant owners, then, are aware of the impact of

a. the fundamental attribution error.
b. the power of the situation.
c. hindsight bias.
d. confirmation bias.
e. diffusion of responsibility.

5. In a research study, Dr. Regalis has participants listen to different kinds of music while she uses a brain scan to examine their brain functioning. Dr. Regalis is most likely studying which part of the brain?

a. Temporal lobe
b. Occipital lobe
c. Broca’s area
d. Motor cortex
e. Corpus callosum

6. As a patient experiences an anxiety attack, he may experience a series of changes that are coordinated by the sympathetic nervous system. Which one of the following would the patient experience?

a. Decreased heart rate
b. Slower breathing
c. Decreased salivation
d. Constricted pupils
e. Increased rate of digestion

7. Joanna’s grandmother told her, “When we were little, we couldn’t afford new clothes, so our mother made us dresses out of potato sacks.” Joanna’s great-grandmother’s ability to envision how a potato sack could be used as material for a dress suggests that she was able to overcome

a. confirmation bias.
b. functional fixedness.
c. algorithms.
d. divergent thinking.
e. belief bias.

8. Research has found that individuals suffering from schizophrenia have an excess number of receptors for the neurotransmitter

a. acetylcholine.
b. norepinephrine.
c. GABA.
d. dopamine.
e. serotonin.

9. Modern psychodynamic counselors are likely to emphasize

a. the role of the id, ego, and superego.
b. the importance of early childhood experiences.
c. long, intensive therapy sessions over a period of many years.
d. fixations that may have stemmed from repressed sexual urges.
e. a patient’s responses to Rorschach inkblots.

0. Which of the following is an example of variable-ratio reinforcement?

a. College acceptance letters arrive around the date of April 1.
b. Percy gives his dog a cookie whenever his dog walks by strangers without barking.
c. Esmeralda disliked the substitute teacher, so she scowled every time she looked at him.
d. Judy discovered a shark’s tooth after several hours of searching for one on the beach.
e. When Stu had been working on his homework for one hour, his mother allowed him to go outside and play.

1. What perspective is sometimes referred to as the “third force,” since it offered a more optimistic alternative to Freud’s psychoanalysis and Skinner’s behaviorism?

a. Biological psychology
b. Humanistic psychology
c. Cognitive psychology
d. Evolutionary psychology
e. Social-cultural psychology

2. The type of therapy that is most likely to emphasize a social-cultural approach by focusing on the patient’s environment is

a. family therapy.
b. rational-emotive behavioral therapy.
c. cognitive therapy for depression.
d. psychopharmacological treatments.
e. aversive therapy.

3. Which part of the brain would be most involved in maintaining homeostasis in body temperature?

a. Prefrontal cortex
b. Temporal lobe
c. Thalamus
d. Hypothalamus
e. Amygdala

4. Unexplained physical symptoms, including headaches, pain, and digestive problems, which cannot be explained by physical or mental causes, may be diagnosed as

a. depressive disorders.
b. personality disorders.
c. somatoform disorders.
d. dissociative disorders.
e. eating disorders.

5. A psychologist who uses aversive conditioning to treat a child’s bed-wetting problem is using which of the following approaches?

a. Cognitive
b. Biological
c. Behavioral
d. Evolutionary
e. Social-cultural

6. Psychologist David Wechsler has created tests for adults and children that are designed to reveal their

a. intelligence.
b. aptitude.
c. achievement.
d. personality characteristics.
e. symptoms of psychological disorders.

7. In order to follow the ethical principles for research as established by the APA, psychologists should

a. recruit participants for experiments by placing ads in college newspapers.
b. publish the full results, including participant information, of their research online.
c. keep their operational definitions secret so that they cannot be copied by other researchers.
d. debrief the participants after the conclusion of the research.
e. allow minors to choose to be participants if they wish to.

8. Which of the following statements is most typical of the approach of a cognitive therapist?

a. "Let's go back to your statement about your happiness as a child."
b. "When you say 'No one likes me' that's illogical, because you do have close friends."
c. "What I hear you saying is you are angry, and I can hear the frustration in your voice."
d. "I'm going to start teaching you to relax, and then we'll slowly deal with your phobia."
e. "I think that prescribing you an SSRI will increase your positive mood over the next few weeks."

9. Dr. Alscott has examined two sets of data from his research. In the first set, the standard deviation was very small, while in the second set there was a much larger standard deviation. Based on this information, what conclusion can be drawn from these two sets?

a. The median was greater than the mean in the second set.
b. The mean was greater than the median in the second set.
c. The standard deviation in both sets revealed a positive correlation between the data.
d. Most data points were closer to the mean in the first set than in the second.
e. Most data points were closer to the mean in the second set than in the first.

0. “The curious paradox is that when I accept myself just as I am, then I can change.” This core idea in humanistic psychology is a quotation from

a. Sigmund Freud.
b. Carl Rogers.
c. Aaron Beck.
d. Carl Jung.
e. B. F. Skinner.

1. Hans Selye argued that our bodies produce a similar reaction to all kinds of stress, and the longer this response continues, the more exhausted we become. He named this process

a. the opponent-process theory.
b. systematic desensitization.
c. the general adaptation syndrome.
d. the global assessment of functioning.
e. triarchic intelligence.

2. “Both the left and the right hemisphere may be conscious simultaneously in different, even in mutually conflicting, mental experiences that run along in parallel.” This quotation by neuropsychologist Roger Sperry refers to his Nobel Prize–winning research on the effects of severing which part of the brain?

a. Amygdala
b. Brainstem

c. Corpus callosum
d. Thalamus
e. Pituitary gland

3. Martin Seligman developed the concept of learned helplessness, the tendency of organisms to give up in situations in which they feel their efforts make no difference. This concept is closely linked to which of the following psychological disorders?

a. Agoraphobia
b. Schizophrenia
c. Major depressive disorder
d. Generalized anxiety disorder
e. Narcissistic personality disorder

4. John Watson's development of the concept of behaviorism was influenced most strongly by the work of

a. Wilhelm Wundt.
b. the Gestalt psychologists.
c. John Locke.
d. B. F. Skinner.
e. Ivan Pavlov.

5. Psychologists Walk and Gibson attempted to determine whether infants had developed the ability to perceive depth by

a. having them crawl over what appeared to be a sharp ledge.
b. measuring how long they looked at novel stimuli.
c. throwing soft foam balls to them and seeing how they would react.
d. showing them a simulation of birds flying at their faces.
e. seeing if they reached for a toy when it was held slightly beyond the reach of their arms.

6. Systematic desensitization would most likely be used as a treatment for which of the following disorders?

a. Arachnophobia

b. Schizophrenia
c. Bipolar disorder
d. Hypochondriasis
e. Tardive dyskinesia

7. A manager at an ice cream store wants to increase sales, so he creates a program to rank his employees' sales. His goal is to give a cash prize each week to the employee who has sold the highest number of ice cream cones. His strategy is based on the idea of

a. the life story approach.
b. intrinsic motivation.
c. extrinsic motivation.
d. the collective unconscious.
e. self-efficacy.

8. The fire alarm has gone off so many times in their new school that Susannah and Tia don't even flinch anymore when they hear it. They even remained in the school library during a fire drill because they assumed it was another malfunction. Their failure to respond like they once did to the fire alarm shows the process of

a. acquisition.
b. discrimination.
c. accommodation.
d. extinction.
e. assimilation.

9. Dr. Anders wants to investigate how people of different ages communicate via the Internet, so she does an experiment with three groups of three different ages: 18- to 21-year-olds, 47- to 50-year-olds, and 75- to 78-year-olds. Concurrently comparing how people of different ages behave is an example of which of the following kinds of research?

a. Case study
b. Longitudinal

c. Cross-sectional
d. Factor analysis
e. Qualitative

0. In studies, reminding female test-takers that women historically have done poorly on a similar test can lead to lower test performance—particularly when compared with the scores of women who weren’t given such information. This decline in performance is an example of

a. stereotype threat.
b. hindsight bias.
c. the mere exposure effect.
d. social facilitation.
e. negative transference.

1. Research suggests that there is a connection between parenting style and social skills. Children with lower scores on measures of social skills and self-esteem tend to have parents who are

a. authoritative.
b. permissive.
c. authoritarian.
d. neglecting.
e. demonstrative.

2. Dr. Pilai worked with the government to create new standards for people seeking jobs as airport security screeners. She included assessments in the interview process, designs for the flow of the security process itself, and measures for evaluating the job performance of these screeners. Which psychology career category best fits Dr. Pilai’s work?

a. Developmental
b. Clinical
c. Forensic
d. Industrial-organizational
e. Community

3. Which emotion theory places the greatest emphasis on physiological changes happening first, which are then followed by an experience of an emotion?

a. Schachter-Singer theory
b. James-Lange theory
c. Cannon-Bard theory
d. Arousal theory
e. Incentive theory

4. Although the group of senior citizens beat the teenagers in a trivia contest based on history, they were not nearly as successful in a competition that required them to quickly learn the rules of a new video game. This is most likely due to the decline of which of the following as humans age?

a. Learned helplessness
b. Cognitive dissonance
c. Fluid intelligence
d. Crystallized intelligence
e. Elaborative rehearsal

5. Which of these statements is most accurate about REM sleep?

a. These periods are the longest at the beginning of the sleep period, then get shorter through the night.
b. These periods are the shortest at the beginning of the sleep period, then get longer through the night.
c. During these periods, brain activity is as reduced as muscle activity.
d. The brainstem continues to pass on motor activity signals to the rest of the body during REM sleep.
e. The dreams during this stage are frequently interrupted by sleep spindles.

6. Random-dot stereograms are pictures that have an image hidden among the dots. Humans can often see these hidden images because each eye has a slightly different image projected on its retina, allowing us to see depth. Which term best describes this process?

a. Motion parallax
b. Convergence
c. Retinal disparity
d. Relative height
e. Linear perspective

7. A therapist tells a CEO that the reason he yells and screams at his staff is due to behavior he learned as a child. When he was a child, he threw temper tantrums in order to get his way. What is the term for this defense mechanism?

a. Regression
b. Reaction formation
c. Projection
d. Rationalization
e. Sublimation

8. During a dental procedure, Xavier is injected with a drug that is designed to greatly reduce his pain by interfering with the sending of pain signals. At the neural level, the drug is preventing

a. action potentials from being transmitted.
b. neurotransmitters from being reabsorbed by neurons.
c. potassium ions from being released at the terminal buttons.
d. pain signals from being clearly interpreted in the sensory cortex.
e. the myelin sheath from protecting the axon.

9. A babysitter cuts a sandwich into three equal pieces, then keeps two and gives one to the child she is caring for. The child is upset that this is unfair, so the babysitter divides the child’s piece into two. Since each of them now has two pieces, the child is content. According to Jean Piaget, this is because the child lacks

a. accommodation.
b. assimilation.
c. formal operational knowledge.

d. sensorimotor ability.
e. conservation.

0. A young gymnast works out many hours each day to prepare for a national competition. This schedule means that she has to forgo opportunities to socialize with her peers, and makes it hard to have a romantic relationship. The gymnast’s willingness to give up some things that would make her feel less lonely and separated in order to pursue athletic achievements is at odds with whose theory of human motivation?

a. Abraham Maslow
b. Henry Murray
c. Philip Zimbardo
d. David McClelland
e. Solomon Asch

1. Seven-year-old Daniel was able to see that the dot-to-dot puzzle was going to form a picture of a tiger even before he started drawing on the puzzle. Which Gestalt principle helped Daniel perceive the tiger from all the unconnected dots?

a. Proximity
b. Continuity
c. Bipolar cues
d. Retinal disparity
e. Closure

2. In an experiment by Stanley Schachter and Jerome Singer, participants labeled their arousal as joyous or irritable, depending on the people they were with. This experiment established that emotions are not only physiological but are also

a. psychodynamic.
b. humanistic.
c. biological.
d. cognitive.

e. behavioral.

3. A tumor cut off bloodflow to a small section of Gia’s brain, and as a result she struggled to understand the words that were being spoken to her. The damage to Gia’s brain was probably localized in her

a. Wernicke’s area.
b. Broca’s area.
c. hippocampus.
d. hypothalamus.
e. brainstem.

4. According to the behavioral perspective, the purpose of punishment is to

a. make a person sorry for the behavior he has committed.
b. associate a positive consequence with a negative consequence.
c. make a behavior less likely to happen again.
d. allow the behavior to only occur again during a spontaneous recovery.
e. extinguish the response permanently.

5. When Eli initially joined an online group that was working against increased government spending, he only had mild views on the topic. If he continues in the group and rarely gets information from alternate sources with opposing views, what might be the outcome?

a. He might become deindividuated and express views against the group’s beliefs.
b. He might use social facilitation to spread the group’s views more widely online.
c. He might use confirmation bias to seek out sources that challenge his beliefs.
d. His views and the group members’ views might become more similar and more intensely felt over time.
e. His views and the group members’ views might become more varied and less intensely felt over time.

6. When seeking to hire a new creative director for an advertising agency, Amina decided that she wanted to find a person who could devise numerous ways to solve problems. A person talented in this area would most likely be good at

a. divergent thinking.
b. convergent thinking.
c. belief perseverance.
d. solving crossword puzzles.
e. doing arithmetic.

7. The personality test that is based on the writings of Carl Jung is the

a. Minnesota Multiphasic Personality Inventory.
b. Wechsler Adult Intelligence Scale.
c. Rorschach inkblot test.
d. Thematic Apperception Test.
e. Myers-Briggs Type Indicator.

8. Jason was watching the TV news, which showed footage of a young man running away from the police. "He's running away, so he must be a bad man," said Jason to his father. Jason's statement is an example of

a. the availability heuristic.
b. the representativeness heuristic.
c. stereotype threat.
d. the fundamental attribution error.
e. cognitive dissonance.

9. The sound of a sizzling steak or the smell of a warm apple pie might make people want to eat those items. In the study of motivation, the sound and smell are considered to be

a. incentives.
b. arousal-inducing.
c. drives.
d. self-actualization needs.
e. fixed action patterns.

0. In the early twentieth century, French psychologists led by Alfred Binet developed the first test for intelligence to be given to French school children for the purpose of

a. selecting the most capable to be trained as future leaders.
b. identifying those who might be wasting their talents and not taking school seriously.
c. testing whether French teachers merited higher pay.
d. evaluating the quality of French schools.
e. finding children who were struggling academically.

1. “We were not surprised to discover that contact comfort was an important basic affectional or love variable, but we did not expect it to overshadow so completely the variable of nursing . . .” This quotation was written by which of the following psychologists?

a. Harry Harlow
b. Konrad Lorenz
c. B. F. Skinner
d. John B. Watson
e. Mary Ainsworth

2. A researcher finds a difference between an experimental group and a control group that is less likely due to chance and more likely due to the manipulation of the independent variable. This finding then is most likely to be

a. a replication.
b. statistically significant.
c. below the margin of error.
d. reliable, but not valid.
e. valid, but not reliable.

3. The mere exposure effect helps explain why the most important predictor of whether two people become friends is

a. similarity of religious and political views.
b. similar interests in the arts and culture.

c. their physical attractiveness.
d. their social status and level of income.
e. their proximity to each other.

4. Albert Bandura believed that children could learn not only by doing behaviors themselves, but also by watching models perform those behaviors. Bandura's work expanded the idea of learning to include

a. observational learning.
b. classical conditioning.
c. operant conditioning.
d. latent learning.
e. rote learning.

5. Which of the following is an example of a self-fulfilling prophecy?

a. David has had trouble in math in the past, so in his new math class he gives up on the first day.
b. Ivy does not think her teacher has treated her fairly, so she complains to her principal.
c. Samuel's teacher puts him in a group with struggling students, and Samuel, normally a good student, responds by doing very poor work. The next week he is placed in the same group.
d. Rachel writes a letter to the editor about her concerns with the city council, and as a result her social studies teacher praises her in class.
e. Nyah's father takes her out of an advanced class because she is struggling at first, but she responds by working even harder and making better grades in all of her classes.

6. Noam Chomsky's beliefs about language are based on the idea that

a. language is only possible during a critical period, and not afterward.
b. simple mastery of phonemes and morphemes does not represent a true language.
c. the rules of syntax are more important than semantics in understanding language.
d. language is innate and we all share a universal grammar.

e. language is just as possible in animals as in humans, given enough time and training.

7. Paul was unable to correctly identify the right shade of blue his wife wanted at the paint store, so he purchased various hues and brought them home. The distinctions among the similar shades of blue apparently fell below Paul's

a. signal detection.
b. absolute threshold.
c. difference threshold.
d. excitatory level.
e. inhibitory level.

8. Teachers at York High School were dismayed at a new test they would be required to take to demonstrate their ability as educators. Rather than a test of content knowledge or of teaching techniques, the new test would measure their reaction time to a series of rapidly flashed abstract images—not a skill they normally need in the classroom. Despite the assurances of the test's creator, the teachers argued that a test like this would have low

a. content validity.
b. predictive reliability.
c. split-half reliability.
d. test-retest reliability.
e. psychometric ratings.

9. In Stanley Milgram's experiments on obedience, he discovered that participants were less obedient when

a. the person giving the orders was close at hand and was perceived to be a legitimate authority figure.
b. the authority figure was supported by a prestigious institution.
c. the victim was depersonalized or at a distance.
d. Milgram dissociated his experiments from Yale University.
e. there were no role models for defiance.

0. The work of Elizabeth Loftus and other researchers has led to significant changes in the way courts and police officers think about

a. the traumatic effects of solitary confinement.
b. whether people with schizophrenia can be forced to take medication against their will.
c. whether the insanity defense is legitimate for legally insane individuals.
d. whether people should be forced to testify against their spouse on the witness stand.
e. the accuracy of eyewitness testimony.

1. The developmental theories of Lev Vygotsky differed from those of Jean Piaget in that Vygotsky

a. emphasized the role of the social environment.
b. thought that Piaget ignored the psychosexual development of children.
c. questioned Piaget's focus on adult development.
d. focused more on moral development.
e. thought that the spiritual component of children's growth was essential.

2. Dorothea Dix was a passionate advocate for

a. reform in the treatment of the mentally ill.
b. the elimination of culturally-biased IQ tests.
c. identifying and reducing the self-fulfilling prophecy in schools.
d. changing the way disorders are classified in the DSM-5.
e. creating an alternative to the use of psychopharmacological medication.

3. For those who focus on the biological approach, important evidence for whether someone who has been diagnosed with depression is improving is

a. the quality of their statements about their own abilities and attitudes.
b. whether the number of contacts with their friends and families has

increased.

c. whether they have begun to establish and work toward long-term goals.
d. whether the serotonin levels in their blood have increased.
e. if they have no suicidal thoughts or intentions.

4. Instead of methodically poring through the atlas to find the correct map, Ivan just flipped to the section of the book where he thought it might be. Using a strategy based on a hunch rather than examining each page carefully involves the use of

a. an algorithm.
b. a heuristic.
c. an “Aha!” moment.
d. insight.
e. framing.

5. On the very first day of class, Mr. Boyarsky gave his students a test. When some complained, he responded that he wanted to know what their talents were, so he was giving them a test to predict what kind of skills they might learn best, and what kinds of jobs they might like to do one day. Mr. Boyarsky’s test was

a. an aptitude test.
b. an intelligence test.
c. an achievement test.
d. a personality test.
e. a projective test.

6. When basketball star Michael Jordan graduated from college as one of a small number of geography majors, the average starting salary for a geography major soared by several hundred thousand dollars. In a situation like this, where one unusual bit of data greatly inflates the average, it is important to use which measure of variation?

a. Mean
b. Median

c. Range
d. Standard deviation
e. Mode

7. Damage to what part of a neuron might result in slowed or incomplete neural transmission along the axon?

a. Cell body
b. Mitochondria
c. Dendrite
d. Myelin sheath
e. Synapse

8. Dr. Warren is testing to see if there is a relationship between the consumption of caffeine and memory. She randomly divides 300 participants into three groups and gives each participant an energy drink to consume. Some of the drinks have high levels of caffeine, some have medium levels, and some have none at all—but they all taste the same. About 30 minutes later, she has the participants play a memory game on the computer where they have to match faces and names together. At the end of the game, the computer thanks them for playing, and their scores are sent to Dr. Warren's lab. The dependent variable in the experiment is

a. how quickly the participants matched the names and faces.
b. the participants' scores from the memory game.
c. the amount of caffeine they consumed.
d. their explanations about how they played the game.
e. the amount of caffeine they consume in a typical week.

9. The independent variable in the experiment described in question 98 is

a. how quickly the participants matched the names and faces.
b. the participants' scores from the memory game.
c. the amount of caffeine they consumed.
d. their explanations about how they played the game.
e. the amount of caffeine they consume in a typical week.

0. A person who has an external locus of control is most likely to explain success or failure on a math test as due to

a. how difficult the questions were.
b. whether he had effectively studied enough.
c. whether he had been able to understand the course material.
d. how well prepared he had been prior to taking the course.
e. the amount of time he had set aside to study.

Free-Response Questions

1. Psychology professors Elliott and Elizabeth are co-writing a book about what kinds of behaviors lead to feelings of happiness.

A. Explain the type of research studies Elliott and Elizabeth should look for as they investigate behaviors that cause feelings of happiness. Use the following terms in your explanation. Note: Definitions alone will not score.

- Experimental method
- Correlational method
- Operational definition

B. Discuss what Elliott and Elizabeth are likely to learn as they read about studies of the relationship between the following psychological factors and happiness.

- REM sleep
- Serotonin
- Facial feedback effect

2. Charlie has been teaching for 25 years and was just assigned a student teacher, Randy. Charlie wants to advise Randy about effective teaching methods.

A. What advice should Charlie give Randy about the effectiveness of the following kinds of techniques and whether they might help motivate students in their classroom?

- Classical conditioning

- Positive reinforcement
- Positive punishment

B. Randy is interested in teaching students study skills that will help them learn and retain information. Discuss how the following concepts might help or get in the way of effective studying.

- Semantic encoding
- State-dependent memory
- Serial position effect

C. Finally, Charlie wants to advise Randy about how to develop a healthy classroom atmosphere. How could Charlie use the following concepts in his advice about building a supportive classroom culture?

- Ingroup bias
- Superordinate goals

Appendix B: AP® Exam Tips

Unit 1

Module 1

Page 2: To assist your active learning of psychology, Learning Targets are grouped together at the start of each module and then framed as questions that appear at the beginning of the pertinent section of reading. It helps to keep the question in mind as you read through a section to make sure that you are following the main point of the discussion.

Page 6: Memory research reveals a *testing effect*: We retain information much better if we actively retrieve it by self-testing and rehearsing. (More on this in Module 2.) To bolster your learning and memory, take advantage of the self-testing opportunities you will find throughout this text. These Check Your Understanding sections will appear periodically throughout each module. The *Ask Yourself* questions will help you relate the material to your life (making it more memorable). You can check your answers to the *Test Yourself* review questions in Appendix E. (In the e-Book, answers are a click away.)

Page 7: Every question on the AP® psychology exam will reflect the fact that psychology is a science built on the tradition of Wundt and his laboratory. Correct test answers are based on what research has revealed, not on “common sense”!

Page 10: There are lots of important people in psychology. As you study, focus on the significance of their accomplishments. You are more likely to be tested on what a finding means than who discovered it.

Page 12: FRQ stands for “Free-Response Question.” The AP® exam contains two of these essay-style questions, which count for one-third of your final score. The actual FRQs will be complex, requiring you to integrate knowledge from across multiple modules, like the practice questions you will find at the end of each unit in this text. These simpler “Practice FRQs” that appear at the end of each module, along with a sample grading rubric, will help you get started practicing this skill.

Module 2

Page 14: Pay close attention to what your authors, David Myers and Nathan DeWall, are emphasizing as they tell the story of psychology. When they say the nature–nurture issue is the *biggest* issue in psychology, that’s a sign that it’s likely to be covered on the AP® exam.

Page 17: You will see versions of Figure 2.1 throughout the text. Spend some time right now familiarizing yourself with how the figure’s three viewpoints might contribute to behavior or mental processes, the very stuff of psychology.

Page 17: These perspectives will come up again and again throughout your AP® psychology course, and they likely *will* be on the exam. You need to become very comfortable with the meaning of terms such as *behavioral*, *cognitive*, and *psychodynamic.* Ask your teacher for clarification if you are the least bit unclear about what the perspectives mean.

Module 3

Page 25: Take careful note of the fact that psychiatry is a medical specialty. You should be able to summarize the similarities and differences among counseling psychologists, clinical psychologists, and psychiatrists for the AP® exam.

Page 26: You are about to read about a lot of career possibilities in psychology. Note the division between basic subfields and applied subfields. The work of some of these specialties is pretty obvious (it’s not that hard to figure out in general what an *educational psychologist* or a *health psychologist* might do). Questions about psychology’s specialties have previously been on the AP® exam. Devote extra attention to those specialties that may be unfamiliar to you.

Unit 2

Module 4

Page 40: Multiple-choice questions on the AP® exam sometimes test your knowledge of “media myths.” Pay particular attention when psychological findings run counter to “common sense.”

Module 5

Page 42: As you read this module, keep in mind that the scientific method is a set of principles and procedures, not a list of facts. You will be expected to understand how the science of psychology is done, not just what it has discovered. The AP® exam frequently asks questions regarding research design in the multiple-choice and free-response sections.

Module 6

Page 51: This is the first of *several* times in your psychology course that you will see something labeled as being positive or negative. We often think that if something is positive it is good and if it’s negative it’s bad. That is rarely the case in this course. Here, positive and negative refer only to the direction of the correlation. They say nothing about whether the relationship is desirable or not.

Page 52: Take note of how much emphasis is put on this idea; correlation and association do not prove a cause-effect relationship. This has been on the AP® exam in the past.

Page 56: The identification of independent and dependent variables is the single most likely concept to be tested on the AP® exam. Experiments are critical to psychology, and independent and dependent variables are critical to experiments.

Module 7

Page 60: Table 7.1 summarizes 13 pages of coverage. Spend some time with it, as it is information you will likely encounter on the AP® exam.

Module 8

Page 71: Sometimes a phrase that is frequently used in the media has a more specific meaning when used in psychology. That’s the case with the phrase “statistically significant.” Make sure you know the precise meaning of this. It has been on the AP® exam in the past.

Unit 3

Module 9

Page 80: There is a ton of vocabulary in this unit and in psychology. However, learning vocabulary is really not so hard: The secret is to work on it every day. Try flash cards. Work with a study buddy. Impress your non-psych friends with your new vocabulary. Just don’t leave it until the night before the test. If you rehearse the vocabulary throughout the unit, you will do better on the unit test. Don’t just reread the flash cards, but rather quiz yourself on them or paraphrase them in your own words. The big bonus is that you will also retain far more information for the AP® exam.

Page 85: Note the important shift here. So far, you have been learning about how just one neuron operates. The action potential is the mechanism for communication *within* a single neuron. Now you are moving on to a discussion of two neurons and how communication occurs *between* them—very different, but equally important. Both ideas are important for the AP® exam.

Page 87: As the text indicates, there are dozens of different neurotransmitters. Though there’s no way to predict exactly which ones you’ll see on the AP® exam, it’s quite possible you will be asked about the neurotransmitters in Table 9.1.

Page 88: Be very clear on this. Neurotransmitters are produced inside the body. They can excite and inhibit neural communication. Drugs and other chemicals come from outside the body. They can have an agonistic effect or an antagonistic effect on neurotransmission. Students have confused these concepts on the AP® exam.

Module 11

Page 101: Your authors, David Myers and Nathan DeWall, are about to take you on a journey through your brain. Focus on the name of each part, its location within the brain, and what it does. Then it’s time to practice, practice, practice. The brain structures have been on previous AP® exams.

Module 13

Page 121: The classic split-brain studies are likely to show up on the AP® exam.

Page 123: Notice that David Myers and Nathan DeWall never refer to your left brain or your right brain. You have two brain hemispheres, each with its own responsibilities, *but you only have one brain*. It’s very misleading when the media refers to the left brain and the right brain, and this happens frequently. When studying for the AP® exam, try to stay away from psychology myths.

Page 125: Dual processing is another one of those big ideas that shows up in several units. Pay attention for the AP® exam!

Module 14

Page 136: Heritability is an important but challenging concept. The key thing to remember is that heritability refers to variation within a group. It does not refer to the impact of nature on an individual. Be clear on both what it is and what it isn't.

Unit 4

Module 16

Page 159: You may wish to think about how the information on selective attention relates to something a little less dangerous: studying. The same principles apply. The more time you spend texting, tweeting, and social networking, the less focused you'll be on the material you're trying to master. A better strategy is to spend 25 minutes doing schoolwork and schoolwork alone. Then you can reward yourself with a few minutes of online time.

Module 18

Page 178: There's a lot of vocabulary here. Make sure you understand the name and the function of each part of the eye. To learn how all the parts fit together, it may help to make rough sketches (you don't need to be an artist to try this!) and then compare your sketches with Figures 18.3 and 18.4. You'll be better off making several quick, rough sketches than one time-consuming, nicely drawn one.

Module 19

Page 188: The Necker cube is an excellent vehicle for understanding the distinction between sensation and perception. Students often get these terms confused. The only visual stimuli are the blue wedges. The circles, lines, and cube are all the products of perception—they are in your mind and not on the page.

Page 191: The illustrations in Figure 19.6 provide you with excellent opportunities to practice identifying monocular depth cues. To really demonstrate your understanding, look for these cues in other drawings and photographs. There are almost always cues to identify. This practice will help you master the terms for the AP® exam.

Module 20

Page 198: Pay attention to how many pages are devoted to each of the senses. Not only does this represent the complexity of the sensory system, it also represents how likely you are to find questions about that system on the AP® exam. Given that more pages are devoted to vision than hearing, there are likely to be more exam questions on vision.

Page 199: Note that both light and sound travel in waves. In each case, understanding the meaning of varying amplitude and length of the waves is important for the AP® exam.

Unit 5

Module 22

Page 224: Note that our modern-day understanding of the unconscious is very different from Sigmund Freud’s theory of the unconscious (Module 55). Freud believed the unconscious was a hiding place for our most anxiety-provoking ideas and emotions, and that uncovering those hidden thoughts could lead to healing. Now, most psychologists simply view the unconscious track as one that operates without awareness. Make sure you keep these two ideas of the unconscious straight. Both interpretations could be seen on the AP® exam.

Page 225: Psychological research corrects the mistaken popular belief that hypnosis or other methods can be used to tap into a pure and complete memory bank. You will learn much more about how memory really works when you get to Unit VII. The topic of hypnosis has been on the AP® exam, so become knowledgeable about it.

Module 23

Page 234: Study this cycle of sleep carefully. One common mistake that students make is to believe that REM sleep comes directly after deep NREM-3 sleep. As you can see, it does not. Generally, NREM-2 follows NREM-3. Then comes REM. This clarification will help for the AP® exam.

Module 24

Page 242: Make sure you get a good night's sleep before the AP® exam!

Page 246: The AP® exam could have you identify and differentiate the sleep disorders. For example, you might be asked to explain the difference between a night terror and a nightmare.

Module 25

Page 255: These three categories—depressants, stimulants, and hallucinogens—are important. There are likely to be questions on the AP® exam that will require you to know how a particular psychoactive drug is classified and what affect the drug has on the body.

Page 260: Figure 25.3 is an excellent review of how neurotransmitters work. If there is any part of this that you don't understand, head back to Module 9 for a complete explanation. Neural communication is a topic that has been on the AP® exam.

Unit 6

Module 26

Page 271: The AP® exam could have you differentiate similar concepts from various units. For example, it's easy to confuse *habituation* with *sensory adaptation*, a concept from Unit IV. Recall that sensory adaptation occurs when one of your sensory systems stops registering the presence of an unchanging stimulus—when you go swimming in a cool pool, for example, the water soon stops feeling cool. Habituation, like sensory adaptation, involves a diminished response, but in this case it's a form of learning. If you're exposed to the same stimulus over and over, your response decreases. A friend might sneak up and startle you by yelling "Boo!" You will probably startle less when he tries it again two minutes later. That's habituation.

Page 275: You may find it helpful to note that spontaneous recovery is, in fact, spontaneous (Figure 26.6). Notice that the extinguished conditioned response returns without any additional pairing with the unconditioned stimulus. It is not a form of acquisition.

Page 277: Generalization and discrimination are introduced in this module, but they don't just apply to classical conditioning. These two concepts will show up in other types of learning as well. It is important that you understand this for the AP® exam.

Module 27

Page 286: Prepare to identify specific examples of positive and negative reinforcements. Pay particular attention to Table 27.1 for guidance.

Page 288: Students sometimes have difficulty with the schedules of reinforcement. The word *interval* in schedules of reinforcement means that an interval of time must pass before reinforcement. There is nothing the learner can do to shorten the interval. The word *ratio* refers to the ratio of responses to reinforcements. If the learner responds with greater frequency, there will be more reinforcements.

Page 289: You must be able to differentiate between reinforcement and punishment. Remember that *any kind of reinforcement* (positive, negative, primary, conditioned, immediate, delayed, continuous, or partial) encourages the behavior. *Any kind of punishment* discourages the behavior. Positive and negative do not refer to values—it's not that positive reinforcement (or punishment) is the good kind and negative is the bad. Think of positive and negative mathematically; a stimulus is added with positive reinforcement (or punishment) and a stimulus is subtracted with negative reinforcement (or punishment).

Module 28

Page 297: You may have to differentiate classical conditioning and operant conditioning on the AP® exam. Classical conditioning is involuntary (respondent) behavior, while operant conditioning is voluntary (operant) behavior.

Module 29

Page 301: In the middle of the twentieth century, behaviorism was the dominant perspective in psychology, with little attention paid to the influence of biology and cognition in learning. Now we know better. As you read through this module, notice how important biological and cognitive factors are for understanding learning. This module reflects the biological and cognitive perspectives of psychology learned about in Unit I. The psychological perspectives (approaches) are frequently seen on the AP® exam (refer to Table 2.1, page 18)

Unit 7

Module 31

Page 327: The next three modules deal with memory. Not only is this a significant topic on the AP® exam, but it is also, for students, one of psychology's most practical topics! As you read, think about how you can apply what you're learning about encoding, storing, and retrieving information—and become a better student.

Page 330: You will see several versions of Figure 31.3 as you work your way through Modules 31, 32, and 33. Pay attention! This model may look confusing now, but it will make more and more sense as its components are described in detail. The three stages of memory and the encoding process will be important to know for the AP® exam.

Page 335: It's not the studying you do in May that will determine your success on the AP® exam; it's the studying you do now. It's a good idea to take a little time each week to quickly review material from earlier in the course. When was the last time you looked at information from the previous units?

Page 336: Are you often pressed for time? The most effective way to cut down on the amount of time you need to spend studying is to increase the personal meaningfulness of the material you're trying to remember. If you can relate the material to your own life—and that's pretty easy when you're studying psychology—it takes less time to master it.

Module 32

Page 344: Figure 32.4 is an excellent summary. Why don't you review it for a few minutes and then see how much of it you can reproduce on a piece of paper? That will give you a good assessment of which parts of the memory process you know and which parts you still need to work on.

Module 33

Page 354: Students frequently get proactive and retroactive interference confused on the AP® exam. Can you differentiate these terms by definition and example?

Module 35

Page 373: Make sure you understand the difference between representativeness and availability heuristics. AP® exam takers have confused them.

Page 376: We're all human—and vulnerable to confirmation bias, overconfidence, and belief perseverance. Can you distinguish these?

Module 36

Page 382: It is sometimes challenging to keep these building blocks straight. Phonemes are sounds. It may help to remember that phones carry sounds. Morphemes have meaning, and both words begin with the letter *m*.

Page 388: You'll notice that even though the brain was one of the major topics in Unit III, it keeps coming up. It's a good idea to go back and review what you learned previously about the brain. Rehearse frequently, and you will not have much to relearn before the AP® exam.

Unit 8

Module 37

Page 403: Read carefully! Homeostasis is *not* a motivation theory, but rather a biological principle that applies to some motivational theories (such as drive-reduction theory). Make sure you can compare and contrast the motivational theories.

Module 39

Page 419: The central principle here is that there are many biological processes that govern human behavior less rigidly than they govern the behaviors of other species. Because of our highly developed brain, sex hormones have less control over our behavior than they do over other animals' behavior.

Module 40

Page 426: Free-response questions on the AP® exam often ask students to apply psychological principles to real-life situations. It's easy to imagine a question that deals with social media.

Module 41

Page 434: Be prepared for at least a multiple-choice question that tests your ability to compare and contrast the James-Lange, Cannon-Bard, and Schachter-Singer Two-Factor theories of emotion.

Page 436: Table 41.1 summarizes of the theories of emotion. They are presented in the order of appearance historically. Notice that cognition, an important factor in the modern theories, is not mentioned in the first two theories.

Page 438: Figure 41.4 compares and contrasts the sympathetic and parasympathetic nervous systems. On the AP® exam you may need to be able to identify which physiological effects occur with each division.

Module 43

Page 454: Be able to differentiate Walter Cannon's fight-or-flight theory and Hans Selye's general adaptation syndrome. These have been on the AP® exam in the past.

Page 460: It’s important to remember the difference between a longitudinal and cross-sectional studies.

Unit 9

Module 45

Page 486: All three of these issues are important for development. Nature and nurture, of course, weave their way through almost every module. Look for the nature–nurture idea throughout this text (and on the AP® exam).

Page 488: Almost every topic in psychology holds personal relevance, but development stands out. As you work your way through this unit, think of how the material relates to you, your relatives, and your friends. The more often you do this, the easier it will be to remember the material.

Module 46

Page 494: Note that maturation, to developmental psychologists, is a biological sequence. This is much more precise than the general notion that maturation means to become more adult-like.

Module 47

Page 499: Be able to identify what it means to assimilate and accommodate schemas. Students have confused these terms on the AP® exam in the past.

Page 501: Careful! *Egocentric* is not the same as egotistical. Egocentric means you can’t take someone else’s point of view. Egotistical means you’re pretty full of yourself.

Page 503: One good way to master the developmental milestones in Piaget’s theory is to see them in action. If you know children of various ages, you can test them using some of the ideas presented in this section. Hide a toy from an infant to see object permanence in action. Pour water between two differently shaped glasses to see if a preschooler understands conservation.

Page 504: Jean Piaget’s developmental stages are likely the topic of at least one AP® exam question. It may help to remember that for Piaget, children are little scientists, and for Vygotsky children are little apprentices.

Module 48

Page 511: Note that temperament is a contribution from the nature side of the nature–nurture debate.

Page 516: It’s understandable if you are struggling to remember the differences between authoritarian and authoritative. Maybe it will help to realize that authoritative parents will engage in a little more give and take, while authoritarian parents do not negotiate. The words *give* and *authoritative* both end in the letters *ive.*

Module 49

Page 521: There is a lot of information in this section. One good way to process these differences and similarities between genders is to consider which facts fit prevailing stereotypes and which don’t.

Module 51

Page 536: Kohlberg’s is an important stage theory. It’s very important to understand that the stage you’re in doesn’t depend on *what* you decide to do (for example, steal the medicine), it depends on *why* you decide to do it.

Module 52

Page 539: Become familiar with Table 52.1, Erikson’s Stages of Psychosocial Development, and be able to identify an individual that may be dealing with the issue in each stage. For example, a teenager may be dealing with the identity versus role confusion issue.

Module 54

Page 561: This section is a good example of the complexity of seemingly simple questions. It seems like one should be able to answer a question like “Does memory decline with age?” with a straightforward *Yes* or *No*. People are complex. Development is complex. We should not be surprised to learn that many factors influence memory in adulthood.

Unit 10

Module 55

Page 579: Be careful: It’s easy to confuse Freud’s three layers of the mind (conscious, preconscious, and unconscious) with the three parts of personality (the impulsive id, conscious ego, and restraining superego).

Page 582: The differences between these defense mechanisms aren’t always clear. For example, *repression* can be found in most examples. Focus on each example’s key feature. If the key feature is seeing your own impulse in someone else, it’s projection. If the key feature is shifting your aggression from one target to another, it’s displacement.

Page 587: It’s very important to understand the differences between Freud’s view of the unconscious and modern psychology’s view of the unconscious. Read this section carefully.

Module 57

Page 597: You are not likely to be asked questions about the specific traits in Figure 57.1. Focus instead on the two main dimensions (extraversion–introversion and stability–instability), and use the traits to get a sense of what the main dimensions mean.

Page 599: Table 57.1 is an excellent summary of the Big Five personality factors and what they mean. Be able to apply the traits to describe behavior. For example, you should be able to explain how high levels of agreeableness might help someone with a particular task.

Module 58

Page 608: Tables 58.1 and 58.2 summarize a whole unit’s worth of information. Review research methods and study the tables well to be clear on the distinctions separating the major approaches to personality.

Module 59

Page 612: Note the difference between *self-esteem* and *self-efficacy*. Although your feeling of self-worth might be related to your beliefs about how competent you are, they are not the same thing.

Unit 11

Module 60

Page 626: Your authors identified three “huge controversies” in the unit opener. All three are covered extensively in this book; be sure you can explain each of them.

Page 630: Familiarize yourself with Table 60.1. Be able to compare and contrast the contributions of the intelligence theorists (e.g., Spearman, Gardner, Sternberg).

Module 61

Page 633: Become familiar with the key contributors in intelligence testing and be able to identify how they differ (e.g., Galton, Binet, Terman).

Page 636: Can you remember why the intelligence test scores in Figure 61.2 are marked off in 15-point intervals? Do the 68 percent and 95 percent areas seem familiar? They should—you’ve seen this graph before. It’s Figure 8.3 from the module on statistical reasoning. Intelligence tests are being used to illustrate that 68 percent of a population will be within one standard deviation of the mean for normally distributed data. Ninety-five percent will be within two standard deviations.

Page 637: Be prepared for a question about the distinction between *reliability* and *validity*, and how psychologists assess each.

Module 62

Page 642: Students tend to confuse crystallized and fluid intelligence. Be able to identify examples of each and whether they generally increase or decrease with age. It might help you to think about how crystals grow larger over time, as does our knowledge (crystallized intelligence).

Module 63

Page 648: Figure 63.1 is worth spending some time on. Try grabbing a study buddy and explaining whether each of the five conditions provides more support for nature or more for nurture. In most cases, it’s some of each and you have to look at comparisons between categories to really be able to draw conclusions.

Unit 12

Module 65

Page 673: Notice that the term *insanity* comes out of the legal system. Insanity in criminal law means that defendants cannot be held accountable for their actions, typically due to mental disorder. It is not a psychological or medical diagnosis and does not appear in the DSM-5.

Module 66

Page 681: The AP® exam may also include references to the *psychoanalytic* and *humanistic* approaches to explaining psychological disorders. Relatively few modern therapists make use of these historically important approaches (see Module 70).

Page 682: This is a good time to review Unit I; specifically, the behavioral, biological, cognitive, and evolutionary perspectives. Be able to discuss what these approaches focus on and how they explain behavior.

Page 682: Review time: Think about the reinforcement examples provided here. Do they describe positive or negative reinforcement?

Module 67

Page 692: This is a good time to review Unit III. Consider how the use of brain scans (such as the MRI and PET) and knowledge about neurotransmitters (such as norepinephrine and serotonine) have helped us understand depression and mania.

Module 68

Page 700: When psychologists refer to “positive” and “negative” schizophrenia symptoms (as with positive and negative *reinforcement* in Unit VI), the terms *positive* and *negative* don’t mean “good” and “bad.” Symptoms are positive and negative in a mathematical sense (adding or subtracting behaviors).

Page 700: Be sure you can differentiate between hallucinations (false sensory experiences) and delusions (false beliefs).

Unit 13

Module 70

Page 723: Most of the treatments discussed in this unit come from the perspectives you’ve been learning about since Unit I. As you reach each major section—like the upcoming one on psychoanalytic and psychodynamic therapy—try to anticipate how someone from that perspective would approach therapy (for example, “What would Freud do?”). This should help you organize and retain the information as you read.

Page 723: As you read, think about the various disorders previously studied and consider how a particular form of therapy might be most effective in treating that disorder.

Page 725: You can remember *A*cceptance, *G*enuineness, and *E*mpathy as “AGE.”

Module 71

Page 730: Before you read the next several pages of this module, you may want to quickly review the material on classical and operant conditioning in Unit VI. Note that behavior therapists, like psychodynamic therapists, focus on childhood experiences, but in a different way. Behavior therapists acknowledge that conditioned responses may result from childhood experiences; psychodynamic therapists instead work on resolving unconscious conflicts stemming from childhood.

Page 734: Behavior therapies focus on what we do. Cognitive therapies focus on what we think. That’s a very basic distinction, but it is critically important for your understanding.

Page 738: Review Table 71.2. You’ll want to be able to compare and contrast the psychotherapies.

Module 73

Page 753: The discussion of drug therapies is a great opportunity for you to review information about neurotransmitters and brain function. See Unit III if you need to brush up on these topics.

Unit 14

Module 74

Page 769: Many students have not heard of the fundamental attribution error before taking a course in psychology. Be sure you can define the concept (which may appear on the AP® exam). Try illustrating this concept using your own attributions and those of others as examples.

Page 771: Be sure you can identify examples of peripheral route persuasion and central route persuasion, and that you understand the difference.

Module 75

Page 780: Three of the most famous research projects in psychology were done by social psychologists, and you’ve now read about them all. Be able to identify the major contributions of Zimbardo (from Module 74), Asch, and Milgram.

Module 76

Page 784: As you work through this material, identify examples of group behavior in your own life. Then, compare your examples with a classmate's. This is a great way to make psychology come alive and to study effectively. If you apply these terms while reading the unit, it will be easier to identify the vocabulary later.

Module 77

Page 793: It's worth spending a little time focusing on the distinction between *discrimination, prejudice*, and *stereotype*. They are related, but different. Be able to distinguish them in examples.

Page 797: Pause for a minute and try to identify examples of the just-world phenomenon, ingroup bias, and scapegoating in your own school.

Module 78

Page 802: Notice that you're back to a nature and nurture analysis again. The biology section is, of course, the nature component. When you get to the psychological and social-cultural factors coming up, that's nurture.

Page 804: This is a good opportunity to review Unit VI yet again. You should go back for a quick review if you don't recognize the basic components of operant conditioning and observational learning in this material.

Page 805: In the hitchhiker experiment described here, can you identify the independent and dependent variables? It's great practice to do this every time you read about an experiment.

Module 79

Page 808: Can you remember the other use of the term *proximity* earlier in the course? It's one of the Gestalt principles from Unit IV.

Appendix D: Preparing for Further Psychology Studies[1]

This appendix was written by Jennifer Zwolinski, University of San Diego.

In Module 3, you learned about the work that different types of psychologists do and where they do it. Here you will find answers to important questions about pursuing the study of psychology: Will psychology be the right college major for you? What are the various levels of psychology education, and what kinds of jobs are available at those levels? What are some ways you can improve your chances for college success, and for admission to graduate school?

The Psychology Major

What Could You Do With a Degree in Psychology?

Lots! As a psychology major, you would graduate with a scientific mindset and an awareness of basic principles of human behavior (biological, developmental, mental disorder–related, social). This background would prepare you for success in many areas, including business, helping professions, health services, marketing, law, sales, and teaching. You could even go on to graduate school for specialized training to become a psychology professional.

How Do You Know If Psychology Is the Right Major for You?

To see if you would be well matched with a major in psychology, start by considering the questions below.

Do you:

- enjoy learning about the ways we think and behave, and why?
- appreciate the value of applying the scientific method to answer questions?
- have an interest in a career that requires interpersonal skills?
- want to learn critical thinking and analytical skills?
- want to learn communication and presentation skills?
- want to gain computer skills in data processing, and research methodology skills such as assessment and statistics?
- want to work in human or animal services?
- have a desire to apply psychological principles to understand or solve personal, social, organizational, or environmental problems?

If you answered "yes" to most or all of these questions, then psychology may be the right major for you.

How Popular Is the Psychology Major?

Psychology is a very popular major. In 2014–2015, psychology was the fourth most popular major—6 percent of all degrees conferred. Business (19 percent), social science and history (11 percent), and health professions and related programs (8 percent) occupied the top three spots (NCES, 2016a). In 2015, more than 117,000 psychology majors graduated with a bachelor's degree from U.S. colleges and universities (NCES, 2016a) (**Figure D.1**).

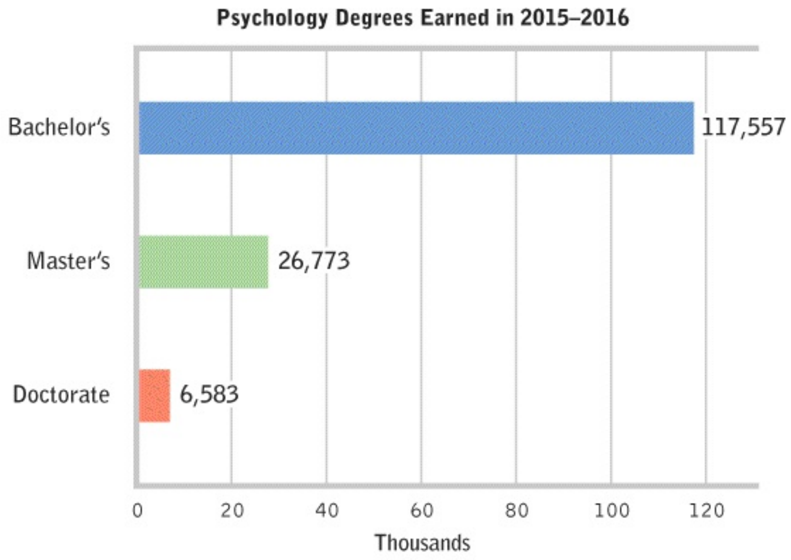

Figure D.1
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from NCES, 2016a, 2016d, 2016e.

Figure D.1 Number of psychology degrees conferred by level of degree: 2015–2016

Given that this number has been steadily increasing since 1970 (NCES, 2016a), it is very likely that psychology will remain a popular major among undergraduate students. The popularity of psychology is observed at the graduate level as well. Over the last decade, the number of graduate degrees in psychology has increased dramatically—by 32 percent at the master's level and 54 percent at the doctoral level (APA Center for Workplace Studies, 2015) (**Figure D.2**). As of 2013, of the 2.5 million workers whose highest degree was in psychology, approximately 1.4 million of them held a bachelor's degree (Christidis et al., 2016a).

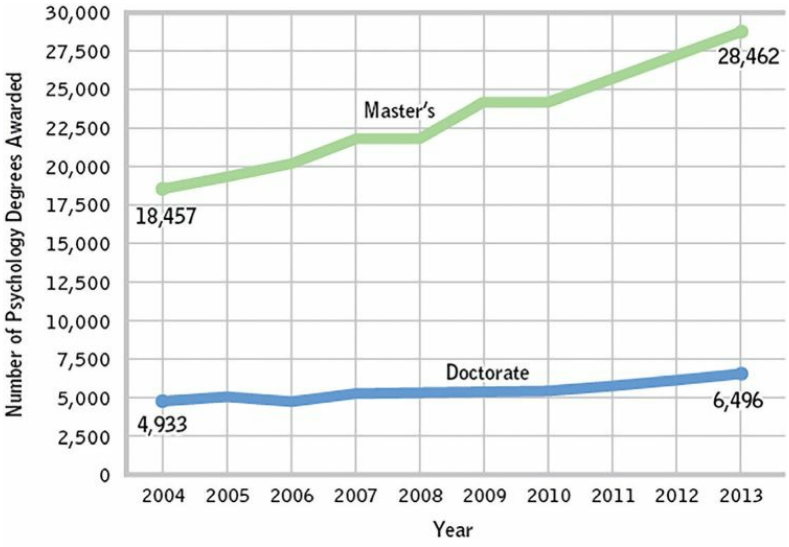

Figure D.2
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from APA Center for Workplace Studies, 2015.

Figure D.2 Number of psychology master's and doctoral degrees awarded by year: 2004–2013

Who Is Studying Psychology at the Undergraduate and Graduate Levels?

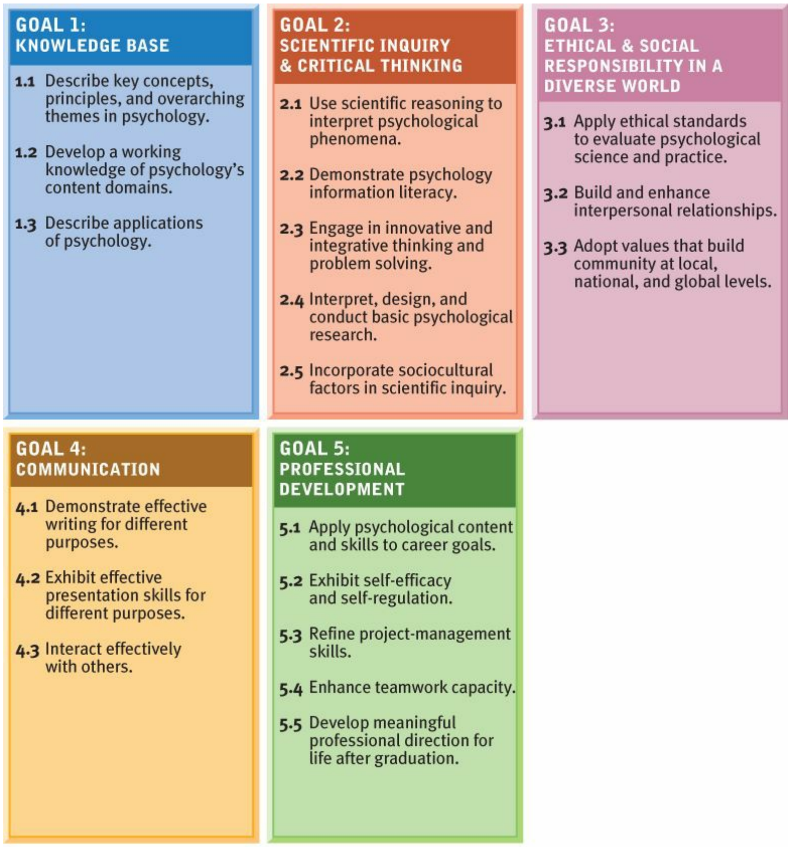
In 2015, a full 77 percent of the graduating psychology majors with bachelor's degrees were women. In that same year, approximately 79 percent of master's degree recipients were women (NCES, 2016b), and 75 percent of doctorate recipients were women (NCES, 2016c). Although 75 percent of all psychology doctorate recipients in 2015 were Caucasian, since 2005, the racial/ethnic diversity of doctorate recipients has grown, with a 12 percent increase among Black/African Americans, a 36 percent increase among Hispanics/Latinos, and a 46 percent increase among Asians (Christidis et al., 2016b).

What Are the Main Reasons That Undergraduate Students Choose to Study Psychology?

One study found that the number one reason psychology majors chose their major was a positive experience in their Introduction to Psychology class (Marrs et al., 2007). Other research has found that the top five reasons students choose a psychology major are that it provides the ability to help others, incorporates interesting subject matter, produces a better understanding of self and others, includes good career or salary potential, and offers the ability to conduct research (Mulvey & Grus, 2010).

What Types of Skills Would You Learn as a Psychology Major?

The wide range of skills that psychology majors develop makes this major a “premier choice” for versatile career preparation (Halonen, 2014). This skill set is guided by the American Psychological Association’s (APA) learning goals and outcomes for psychology majors (**Figure D.3**).



GOAL 1: KNOWLEDGE BASE

1.1 Describe key concepts, principles, and overarching themes in psychology.
1.2 Develop a working knowledge of psychology’s content domains.
1.3 Describe applications of psychology.

GOAL 2: SCIENTIFIC INQUIRY & CRITICAL THINKING

2.1 Use scientific reasoning to interpret psychological phenomena.
2.2 Demonstrate psychology information literacy.
2.3 Engage in innovative and integrative thinking and problem solving.
2.4 Interpret, design, and conduct basic psychological research.
2.5 Incorporate sociocultural factors in scientific inquiry.

GOAL 3: ETHICAL & SOCIAL RESPONSIBILITY IN A DIVERSE WORLD

3.1 Apply ethical standards to evaluate psychological science and practice.
3.2 Build and enhance interpersonal relationships.
3.3 Adopt values that build community at local, national, and global levels.

GOAL 4: COMMUNICATION

4.1 Demonstrate effective writing for different purposes.
4.2 Exhibit effective presentation skills for different purposes.
4.3 Interact effectively with others.

GOAL 5: PROFESSIONAL DEVELOPMENT

5.1 Apply psychological content and skills to career goals.
5.2 Exhibit self-efficacy and self-regulation.
5.3 Refine project-management skills.
5.4 Enhance teamwork capacity.
5.5 Develop meaningful professional direction for life after graduation.

Figure D.3

Figure D.3 APA Guidelines for the Undergraduate Psychology Major: Learning Goals and Outcomes

(APA, 2013. For complete Guidelines, see apa.org/ed/precollege/about/undergraduatemajor.aspx)

Across all occupations, the skill set that twenty-first-century employers value includes social perceptiveness, reading comprehension, critical thinking, and speaking and active listening skills (Carnevale & Smith, 2014). These skills align with APA's learning goals and outcomes (Figure D.3), which means that psychology majors will be well prepared for numerous professional opportunities and a range of graduate training options. In addition to exceptional interpersonal and communication skills, psychology majors develop a number of methodological skills that result from the focus on the scientific study of human and animal behavior. The study of statistics and research methodology contributes to a scientific mindset that emphasizes exploring and managing uncertainty, critical thinking and analytical skills, and logical thinking abilities. The ability to analyze data using statistics, conduct database searches, and integrate multiple sources of information are helpful in a number of professional settings. Prospective employers appreciate the excellent written and verbal communication skills among students who present their research projects at conferences and master APA style.

Career Options with a Degree in Psychology

What Could You Do With a Bachelor's Degree in Psychology?

A psychology major would prepare you for many possible career paths. About 40 percent of students with a bachelor's degree in psychology attend graduate school or receive professional training, which means the majority of psychology majors will be in the job market after graduation (Halonen, 2014). About 10 percent of Americans with a psychology bachelor's degree work in STEM occupations (science, technology, engineering, and math), with over half of that group working in the social sciences. Another 10 percent work in STEM-*related* occupations, with most of that group working in health care (Christidis et al., 2015) (**Figure D.4**). The remaining 80 percent work in non-STEM fields (Christidis et al., 2015). Most individuals with a bachelor's degree in psychology find work in business administration, sales, or education (U.S. Bureau of Labor Statistics, 2015), with many others working in public affairs, the service industries, and computer programming (APA, n.d.). Popular occupations include employment counselor, interviewer, personnel analyst, probation officer, or writer (APA, n.d.). If you choose to work more directly in the field of psychology, a bachelor's degree will qualify you to work as an assistant to psychologists, researchers, or other professionals in community mental health centers, vocational rehabilitation offices, and correctional programs (U.S. Bureau of Labor Statistics, 2015).

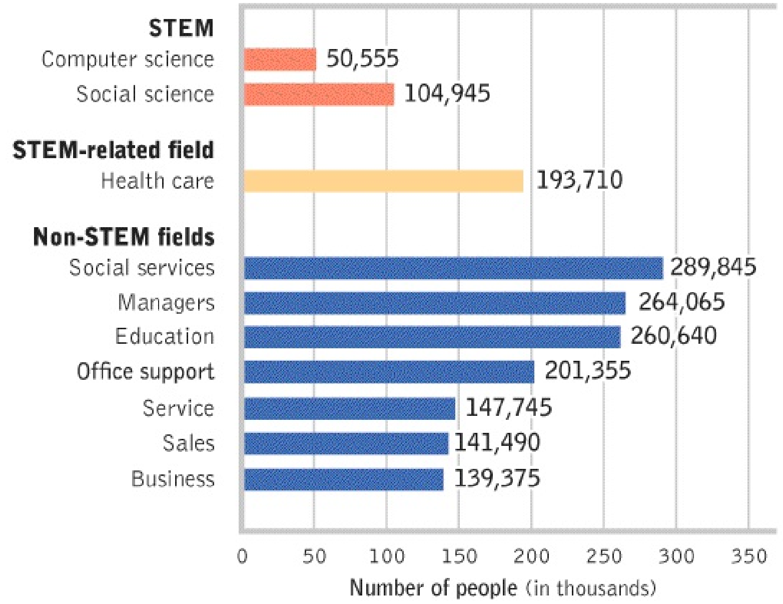

Figure D.4
Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from Christidis, Stamm, & Lin, 2015.

Figure D.4 Where do people work with a bachelor's degree in psychology?

A second option for psychology majors after graduation is to pursue a graduate master's or doctorate degree in psychology. (More on this below.)

A third option is to pursue advanced training in other disciplines such as law, business, education, or medicine.

Drew Appleby provides a list of 300 careers that would be of interest to psychology majors (2016)—including those pursuing advanced degrees. The list includes links for more information about professional responsibilities, salaries, and job outlook for each of these positions. (See teachpsych.org/psycareer.)

According to 2013 data from the National Science Foundation, career paths differ depending on the type of psychology degree that individuals received (**Figure D.5**). For example, about half of individuals with graduate degrees in psychology worked in professional services, which includes positions in health care, financial and legal services, and counseling. In comparison, whereas some individuals with a bachelor’s in psychology worked in professional services, many of them worked in sales, management/supervision, and other work fields (Stamm et al., 2016).

Figure D.5 Where do people work with varying psychology degrees?

How Can You Maximize Your College Success and Later Job Prospects With a Major in Psychology?

Betsy Morgan and Ann Korschgen (2009) offer the following helpful tips for increasing your chances of getting a job after graduation. Many of these tools will benefit students who plan to apply to graduate school as well.

1. **Get to know your instructors.** Talk with them about the field of psychology and get their advice on your career plan. Ask them to support you on an independent study internship or research project. By learning more about your skills and ambitions, faculty members can help you accomplish your goals. This may even result in an enthusiastic reference for future employment.

2. **Familiarize yourself with available resources.** Talk to alumni and senior students. Your college's Career Services can help you identify and market your job skills and emphasize your knowledge and abilities in your resume. They can also help you to network with other alumni who are working in your area of interest who can help you to prepare for the career that you want. I've included some other helpful online resources at the end of this appendix.

3. **Volunteer some of your time and talent to campus or community organizations, such as Psi Chi (the national honor society in psychology) or your college's psychology club.** In addition to showing that you are an active citizen in your department, you will gain important skills, such as meeting and event planning, how to work with a group, and improved communication skills, all of which enhance your marketability.

4. **Participate in an internship experience.** Many employers want students to gain relevant experience outside the classroom. Internships are offered during the school year as well as the summer break. Some are paid and others are not, but you may be able to earn course credit while completing your internship. In addition to gaining relevant work

experience before you graduate, you will increase your network of mentors who can provide supervision and support for your career goals as well as letters of endorsement when you apply for jobs.

5. **Take courses that support your interests and plans.** Although the psychology major offers a range of skills that will benefit you in the job market, don't assume the psychology curriculum will offer all the skills necessary to get a job in your area of interest. Add courses to increase your knowledge base and skills. This will also show prospective employers that your specific interests are in line with the demands of the job.

If you work hard now and plan ahead, you may be able to avoid regrets later. A Pew Research study asked college graduates whether (1) studying more, (2) starting their job search earlier, (3) choosing a different major, or (4) gaining more job experience during college would have helped them to get a better job (Pew Research Center, 2014). About three quarters of the group reported that doing at least one of one of these things would indeed have helped them to earn a better job. Graduates' number one regret? Not getting enough job experience during college.

What Type of Salary Could You Expect With a Degree in Psychology? Would a Graduate Degree Increase Your Income Potential?

In 2013, the average *starting* salary for a BA degree recipient was $35,108 (NCES, 2015). By comparison, the 2013 average starting salary for master's degree recipients was $51,935, and for doctoral recipients was $53,458 (NCES, 2015). In this same year, the median salary for full-time, doctoral-level psychologists was $80,000 (Lin et al., 2017). The highest salaries were for individuals with doctorates in general psychology ($110,000) and industrial/organizational psychology ($108,000), with the lowest salaries for individuals with doctorates in educational psychology ($73,000). Psychologists with a doctoral (Ph.D.) degree had a higher median salary than those with a professional (Psy. D.) degree ($84,000 vs.

$70,000) (Lin et al., 2017). Across a lifetime, individuals with a psychology bachelor’s are expected to earn $2,001,000, whereas individuals with a doctorate in psychology are expected to earn $3,157,000 (U.S. Census Bureau, 2012) (**Figure D.6**). Clearly, earnings tend to increase with education, and higher levels of education will almost always yield greater financial rewards over the course of a career (Carnevale, 2016).

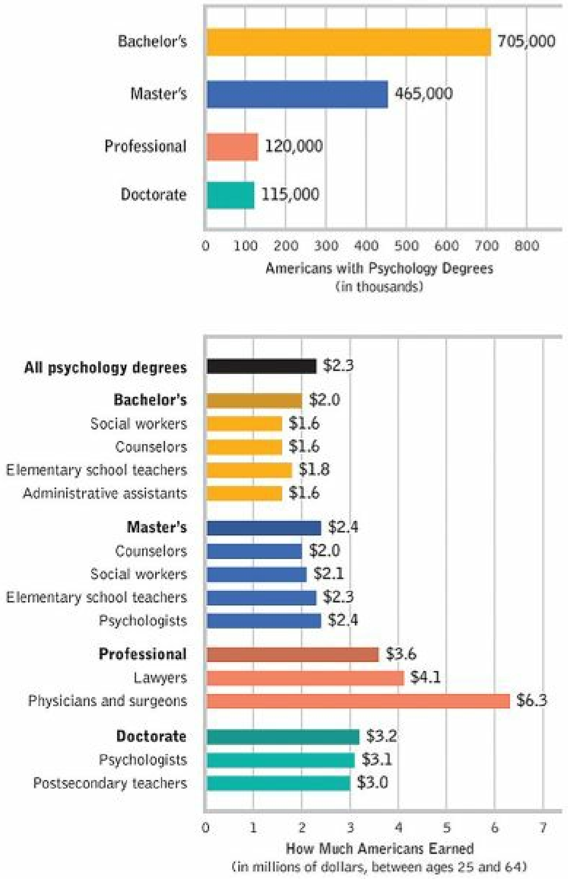

Figure D.6
Myers/DeWall, *Myers’ Psychology for the AP® Course*, 3e,
© 2018 Worth Publishers
Data from U.S. Census Bureau, 2012.

Figure D.6 Salary comparison for psychology degree pathways

Among early-career psychologists, clinical neuropsychologists reported the highest median first year salary of $72,500, followed by clinical child psychologists ($65,850), and clinical psychologists and industrial/organizational psychologists (both $65,000) (Doran et al., 2016).

Psychologists rank number seven (tied with medical scientists) among the top-paying occupations for those with doctoral degrees. The lifetime salary in 2009 dollars was $2,515,000 for graduate level psychologists, compared to the average lifetime salary for all doctoral occupations of $3,252,000 (Carnevale et al., 2011).

Of course, earning potential should not be the only reason that individuals choose a major. Job satisfaction is another important consideration.

What Kind of Job Satisfaction Could You Expect If You Work in a Psychology Field?

In 2015, an impressive 88 percent of U.S. employees reported that they were overall satisfied with their jobs, marking the highest level of job satisfaction in the last 15 years (Society for Human Resources Management, 2016). In a study of 27,000 Americans, the most satisfying jobs were those that involved “caring for, teaching, and protecting others, and creative pursuits” (Smith, 2007, pp. 1–2). Most of the occupations with the highest-ranking happiness levels involved helping others, using technical and scientific expertise, or using creativity (pp. 1–2). A bachelor’s degree in psychology can increase the likelihood that you will be working in a job that fosters these skills (Landrum, 2009).

High levels of job satisfaction have also been observed among individuals who attend graduate school in psychology. In 2009, a full 72 percent of new doctoral recipients indicated that their primary occupation was their first choice. Most new graduates with a Ph.D. are fairly satisfied with their current position in terms of salary, benefits, opportunities for personal development, supervisors, colleagues, and working conditions (Michalski et al., 2011).

Postgraduate Degrees

Why Should You Consider Attending Graduate School in Psychology?

If you choose to earn a graduate degree in psychology, you will be in good company. About 45 percent of those with a bachelor’s degree in psychology or social work go on to graduate school (Carnevale et al., 2015). Those with graduate degrees in psychology earn 33 percent more, on average, than psychology majors with only a bachelor's degree ("By the numbers," 2016). In addition to a higher salary and strong job satisfaction, a graduate degree in psychology will give you proficiency in an area of psychological specialization and increased opportunities to work in diverse areas of psychology. Also, individuals with the highest degrees in psychology have the highest rates of full-time employment (Christidis et al., 2016a).

Job prospects in the field of psychology are much better for individuals with graduate degrees. According to the U.S. Bureau of Labor Statistics (2015), job prospects will be best for those in clinical, counseling, or school psychology positions for candidates with a doctoral or education specialist degree and postdoctoral work experience. Individuals with a master's degree will face keener competition for positions in psychology than those with a doctoral degree.

Employment for psychologists is expected to grow 19 percent from 2014 to 2024, which is faster than average for all occupations. Employment will grow because of increased demand for psychological services in schools, hospitals, social service agencies, and mental health centers (U.S. Bureau of Labor Statistics, 2015).

What's the Difference Between a Master's Degree and a Doctorate Degree in Psychology?

Both degrees would prepare you for more specialized training in psychology and increase your job opportunities in the field of psychology beyond the bachelor's degree.

A master's degree in psychology requires at least two years of full-time graduate study in a specific subfield of psychology. In addition to specialized course work in psychology, requirements usually include practical experience in an applied setting or a master's thesis reporting on an original research project. You might acquire a master's degree to do specialized work in psychology. As a graduate with a master's degree, you might handle research and data collection and analysis in a university, government, or private industry setting. You might work under the supervision of a psychologist with a doctorate, providing some clinical service such as therapy or testing. Or you might find a job in the health, government, industry, or education fields. You might also acquire a master’s degree as a stepping stone for more advanced study in a doctoral program in psychology, which would expand the number of employment opportunities available to you.

It takes more time to complete a doctoral degree in psychology, relative to a master’s degree. Among graduates who earned a research doctorate (Ph.D.) in psychology in 2013, the average time to degree completion was 7 years after starting graduate school, or 8.3 years after finishing their bachelor’s degree (Lin et al., 2017). The doctoral degree you choose to pursue would depend on your career goals. You may choose to earn a doctor of philosophy (Ph.D.) in psychology if your career goals are geared toward conducting research, or a doctor of psychology (Psy.D.) if you are more interested in becoming a practicing clinician. Training for the Ph.D. culminates in a dissertation (an extensive research paper you will be required to defend orally) based on original research. Courses in quantitative research methods, which include the use of computer-based analysis, are an important part of graduate study and are necessary to complete the dissertation. Psy.D. training may be based on clinical (therapeutic) work and examinations rather than a dissertation. Many psychologists who earn a Ph.D. in clinical or counseling psychology conduct research and practice as psychotherapists. If you pursue clinical and counseling psychology programs, you should expect at least a one-year internship in addition to the regular course work, clinical practice, and research. It is important to note, however, that psychologists with Psy.D. degrees are not the only ones who work as psychotherapists; some types of counselors and therapists may practice with only master’s degrees.

Figure D.7 lists by subfield the Ph.D.s earned in the United States in 2012, the most recent year for which these data are available. Among the doctorates awarded in the 2011–2012 academic year, the most popular subfield was clinical psychology, followed by general psychology. Of these doctorates, the majority were classified as research/ scholarship (74 percent), with fewer designated as professional practice (24 percent) or other types (1 percent) (APA Center for Workplace Studies, 2014).

Myers/DeWall, *Myers' Psychology for the AP® Course*, 3e, © 2018 Worth Publishers
Data from National Center for Education Statistics, Integrated Postsecondary Education Data System [IPEDS], 2012 Completion Survey.

Figure D.7 Number of doctorate degrees awarded by psychology subfield in 2012

Preparing Early for Graduate Study in Psychology

Competition for openings for advanced degree programs in psychology is keen. If you plan to go to graduate school after college, there are a number of things you can do in advance to maximize your chances of gaining admission to the school of your choice.

The first step is to take full advantage of your opportunities in high school. By enrolling in challenging elective courses and working hard to develop an academic skill set, you will have paved the way for success in college. Successful students also take the time to learn effective study skills and to establish disciplined study habits. Involve yourself in extracurricular activities, gain some experience in the world of work by taking on a part-time job, and look for opportunities to volunteer in your school and community. In addition to helping you grow as a person, becoming a well-rounded student with high standards helps you to earn scholarships and increases your chances of being accepted by the colleges and universities of particular interest to you.

During your first year at college, continue to maximize opportunities and obtain the experience needed to gain admission to a competitive program. Kristy Arnold and Kelly Horrigan (2002) offer a number of suggestions to facilitate this process:

1. **Network.** Get to know faculty members and the psychology department by attending activities and meetings. This will be especially helpful when you apply to graduate school or for a job, because many applications require two to three letters of reference. Become involved in psychology clubs and in Psi Chi, the national honor society in psychology. These meetings will help you connect with other students who have similar interests and expose you to a broader study of the field.
2. **Become actively involved in research as early as possible.** Start by doing simple tasks such as data entry and data collection, and over time you will be prepared to conduct your own research project under the supervision of a research mentor. Consider applying for summer research positions through your university or from other organizations such as the American Psychological Association Summer Science Fellowship program or the National Science Foundation Research Experiences for Undergraduates (REU) program, which will test your interest in academic careers and build your skills for future study in psychology.
3. **Volunteer or get a job in a psychology-related field.** Getting involved in this way will demonstrate your willingness to apply psychological concepts to real-world settings. Further, it will showcase your ability to juggle a number of tasks successfully, such as those required for work and school—an important skill for graduate school success.
4. **Maintain good grades and prepare early for the GRE.** Demonstrate your ability to do well in graduate school by successfully completing challenging courses, especially those related to your interests. (See "Use Psychology to Become a Stronger Person—and a Better Student" in Module 2, and the final section in Module 33 for tips on how to do well in this and other courses, and how to improve your retention of the information you are learning.) In your junior year of college, you

should begin studying for the Graduate Record Exam (GRE), the standardized test that applicants to graduate school must complete. Many graduate programs in psychology require both the general GRE and the psychology subject tests. If you start preparing early and maintain high grades, you will be ready for success in your graduate school application and study.

For More Information

How Can You Learn More About the Psychology Major and the Field of Psychology?

1. Talk with as many people as possible who have experience in the discipline of psychology. Your psychology teacher or school counselor may have some tips. Try to learn about opportunities to contact psychology majors, graduate students in psychology, psychology instructors and advisors, and other professionals who trained in psychology or who work in the field.
2. Read books, such as those listed at the end of this appendix.
3. Take advantage of online resources, which can help you to determine whether you would be well matched for a major and a career in psychology.
    - Watch online videos showcasing different careers in psychology, such as those found at drkit.org/psychology.
    - Play the Career Interest Game (career.missouri.edu/career-interest-game).
    - Get more information about specific jobs in psychology from the Bureau of Labor Statistics, the Occupational Information Network (O*NET), or the Occupational Outlook Handbook (OOH).
    - Visit the websites of the American Psychological Association (apa.org) and Association for Psychological Science (psychologicalscience.org). The APA has a lot to offer high school

students who are interested in learning more about psychology. To learn more about membership at the high school level (which includes subscriptions to APA journals and mobile apps), visit apa.org/membership/hs-student/index.aspx. You can also become a member of the Psychology Student Network (apa.org/ed/precollege/psn/index.aspx).

- Learn more about the national honor societies in psychology, Psi Chi and Psi Beta.

What Are Some Books That Can Help You to Learn More About the Major, Careers, and Graduate School in Psychology?

American Psychological Association. (2017). *Graduate study in psychology, 2016 edition*. Washington, DC: Author.

Hettich, P., & Landrum, R. E. (2014). *Your undergraduate degree in psychology: From college to career*. Thousand Oaks, CA: Sage.

Kuther, T., (2016). *The psychology majors handbook* (4th ed.). Boston, MA: Wadsworth Cengage.

Landrum, E., & Davis, S. (2013). *The psychology major: Career options and strategies for success* (5th ed.). Upper Saddle River, NJ: Pearson/Prentice Hall.

Morgan, B., & Korschgen, A. (2014). *Majoring in psychology? Career options for psychology undergraduates* (5th ed.). Boston, MA: Pearson.

Silvia, P. J., Delaney, P. F., & Marcovitch, S. (2016). *What psychology majors could (and should) be doing: A guide to research experience, professional skills, and your options after college* (2nd ed.). Washington, DC: American Psychological Association.

Sternberg, R. (2016). *Career paths in psychology: Where your degree path can take you* (3rd ed). Washington, DC: American Psychological Association.

Appendix E: Answers to Test Yourself Questions

Unit I

Psychology's History and Approaches

Module 1 Psychology and Its History

Page 6

Describe what's involved in critical thinking.

nswer: Evaluating evidence, assessing conclusions, and examining our own ssumptions are essential parts of critical thinking.

Page 9

What event defined the start of modern scientific psychology?

nswer: Scientific psychology began in Germany in 1879 when Wilhelm Wundt pened the first psychology laboratory.

Why did introspection fail as a method for understanding how the mind works?

nswer: People's self-reports varied, depending on the experience and the person's ntelligence and verbal ability, and because we often don't know *why* we think or eel the way we do!

The school of _____________ used introspection to define the mind's makeup; _____________ focused on how mental processes enable us to adapt, survive,

and flourish.

nswer: structuralism; functionalism

Page 11

From the 1920s to the 1960s, the two major forces in psychology were _____________ and _____________ psychology.

nswer: behaviorism; Freudian

Module 2 Today's Psychology and Its Approaches

Page 15

How did the cognitive revolution affect the field of psychology?

nswer: It recaptured the field's early interest in mental processes and made them gitimate topics for scientific study.

What is natural selection?

nswer: This is the process by which nature selects from chance variations the aits that best enable an organism to survive and reproduce in a particular nvironment.

What is contemporary psychology's position on the nature–nurture issue?

nswer: Psychological events stem from the interaction of nature and nurture, ther than from either of them acting alone.

Page 19

What advantage do we gain by using the biopsychosocial approach in studying psychological events?

nswer: By incorporating these three key viewpoints, the biopsychosocial approach an provide a more complete view than any one perspective could offer.

The_____________-_____________ perspective in psychology focuses on how behavior and thought differ from situation to situation and from culture to culture, while the _____________ perspective emphasizes observation of how we respond to and learn in different situations.

nswer: social-cultural; behavioral

Page 22

The ______________ ______________ describes the enhanced memory that results from repeated retrieval (as in self-testing) rather than from simple rereading of new information.

Answer: testing effect

What does the acronym SQ3R stand for?

Answer: *S*urvey, *Q*uestion, *R*ead, *R*etrieve, *R*eview

Module 3 Subfields in Psychology

Page 26

Match the specialty on the left with the description on the right.

1. Clinical psychology	**a. Works to create social and physical environments that are healthy for all.**
2. Psychiatry	**b. Studies, assesses, and treats people with psychological disorders but usually does not provide medical therapy.**
3. Community psychology	**c. Branch of medicine dealing with psychological disorders.**

Answer: 1, b; 2, c; 3, a

Page 31

Name each of these subfields: (a) focuses on people and their work environments; (b) studies how people change over the life span; (c) considers the human thinking involved in perceiving, remembering, speaking, and decision making; and (d) focuses on diagnosing and treating psychological disorders.

Answer: These subfields are (a) industrial-organizational psychology, (b) evelopmental psychology, (c) cognitive psychology, and (d) clinical psychology.

Unit II

Research Methods: Thinking Critically With Psychological Science

Module 4 The Need for Psychological Science

Page 40

Why, after friends start dating, do we often feel that we *knew* they were meant to be together?

nswer: We often suffer from hindsight bias—after we’ve learned a situation’s
utcome, that outcome seems familiar and therefore obvious.

Module 5 The Scientific Method and Description

Page 43

What does a good theory do?

nswer: (1) It *organizes* observed facts. (2) It implies hypotheses that offer testable
redictions and, sometimes, practical applications. (3) It often stimulates further
search.

Why is replication important?

nswer: When other investigators are able to replicate an experiment with the same
r stronger) results, scientists can confirm the result and become more confident of
s reliability.

Page 45

We cannot assume that case studies always reveal general principles that apply to all of us. Why not?

nswer: Case studies involve only one individual or group, so we can’t know for
re whether the principles observed would apply to a larger population.

Page 47

What is an unrepresentative sample, and how do researchers avoid it?

nswer: An unrepresentative sample is a group that does not represent the opulation being studied. *Random sampling* helps researchers form a representative ample, because each member of the population has an equal chance of being ncluded.

What are some strengths and weaknesses of the three different methods psychologists use to describe behavior—case studies, naturalistic observation, and surveys?

nswer: *Case studies* offer in-depth insights that may offer clues to what's true of thers—or may, if the case is atypical, mislead. *Naturalistic observation* enables the tudy of behavior undisturbed by researchers. But the lack of control may leave ause and effect ambiguous. *Surveys* can accurately reveal the tendencies of large opulations. But if the questions are leading, or if non-random samples are queried, he results can again mislead us.

Module 6 Correlation and Experimentation

Page 53

You hear the school basketball coach telling her friend that she rescued her team's winning streak by yelling at the players after an unusually bad first half. What is another explanation of why the team's performance improved?

nswer: The team's poor performance was not their typical behavior. The return to heir normal—their winning streak—may just have been a case of regression toward he mean.

Page 55

What measures do researchers use to prevent the placebo effect from confusing their results?

nswer: Research designed to prevent the placebo effect randomly assigns articipants to an *experimental group* (which receives the real treatment) or to a *ontrol group* (which receives a placebo). A double-blind procedure prevents articipants' and researchers' beliefs and hopes from affecting the results, because either the participants nor those collecting the data know who receives the placebo. A comparison of the results will demonstrate whether the real treatment produces etter results than *belief* in that treatment.

Page 57

By using *random assignment,* researchers are able to control for ______________ ______________, which are other factors besides the independent variable(s) that may influence research results.

Answer: confounding variables

Match the term on the left with the description on the right.

1. double-blind procedure

2. random sampling

3. random assignment

a. helps researchers generalize from a small set of survey responses to a larger population

b. helps minimize preexisting differences between experimental and control groups

c. controls for the placebo effect; neither researchers nor participants know who receives the real treatment

Answer: 1, c; 2, a; 3, b

Module 7 Research Design and Ethics in Psychology

Page 64

How are animal subjects and human research participants protected?

Answer: Animal protection legislation, laboratory regulation and inspection, and ocal and university ethics committees (which screen research proposals) work to afeguard animal welfare. International psychological organizations urge researchers nvolving human participants to obtain *informed consent,* protect them from greater-han-usual harm and discomfort, treat their personal information confidentially, and *ebrief* them fully at the end of the experiment.

Module 8 Statistical Reasoning in Everyday Life

Page 72

The arithmetic average of a distribution of scores is the _____________. The score that shows up most often is the _____________. The score right in the middle of a distribution (half the scores above it; half below) is the _____________. We determine how much scores vary around the average in a way that includes information about the _____________ of scores (difference between highest and lowest) by using the _____________ _____________ formula.

nswer: mean; mode; median; range; standard deviation

Can you solve this puzzle? The registrar's office at the University of Michigan has found that usually about 100 students in Arts and Sciences have perfect grades at the end of their first term at the university. However, only about 10 to 15 students graduate with perfect grades. What do you think is the most likely explanation for the fact that there are more perfect grades after one term than at graduation (Jepson et al., 1983)?

nswer: Averages based on fewer courses are more variable, which guarantees a reater number of extremely low and high grades at the end of the first term.

_____________ statistics summarize data, while _____________ statistics determine if data can be generalized to other populations.

nswer: Descriptive; inferential

Unit III

Biological Bases of Behavior

Module 9 Biological Psychology and Neurotransmission

Page 81

What do phrenology and biological psychology have in common?

nswer: They share a focus on the links between the brain and behavior. hrenology faded because it had no scientific basis—skull bumps don't reveal ental traits and abilities.

Page 84

When a neuron fires an action potential, the information travels through the axon, the dendrites, and the cell body, but not in that order. Place these three structures in the correct order.

nswer: dendrites, cell body, axon

How does our nervous system allow us to experience the difference between a slap and a tap on the back?

nswer: Stronger stimuli (the slap) cause more neurons to fire and to fire more equently than happens with weaker stimuli (the tap).

Page 86

What happens in the *synaptic gap*?

nswer: Neurons send neurotransmitters (chemical messengers) across this tiny pace between one neuron’s terminal branch and the next neuron’s dendrite or cell ody.

What is *reuptake*? What two other things can happen to excess neurotransmitters after a neuron reacts?

nswer: Reuptake occurs when excess neurotransmitters are reabsorbed by the ending neuron. They can also drift away or be broken down by enzymes.

Page 89

Serotonin, dopamine, and endorphins are all chemical messengers called ______________.

nswer: neurotransmitters

Module 10 The Nervous and Endocrine Systems

Page 93

Match the type of neuron to its description.

1. Motor neurons

a. carry incoming messages from sensory receptors to the CNS.

3. Sensory neurons	**b. communicate within the CNS and process information between incoming and outgoing messages.**
3. Interneurons	**c. carry outgoing messages from the CNS to muscles and glands.**

nswer: 1, c; 2, a; 3, b

What bodily changes does your ANS direct before and after you give an important speech?

nswer: Responding to this challenge, your ANS *sympathetic division* will arouse ou. It accelerates your heartbeat, raises your blood pressure and blood sugar, slows our digestion, and cools you with perspiration. After you give the speech, your NS *parasympathetic division* will reverse these effects.

Page 94

How does information flow through your nervous system as you pick up a fork? Can you summarize this process?

nswer: Your central nervous system's hungry brain activates and guides the uscles of your arm and hand via your peripheral nervous system's motor neurons. s you pick up the fork, your brain processes the information from your sensory ervous system, enabling it to continue to guide the fork to your mouth. The unctional circle starts with sensory input, continues with interneuron processing by e central nervous system, and finishes with motor output.

Page 96

Why is the pituitary gland called the "master gland"?

nswer: Responding to signals from the hypothalamus, the pituitary releases ormones that trigger other endocrine glands to secrete hormones, which in turn fluence brain and behavior.

How are the nervous and endocrine systems alike, and how do they differ?

nswer: Both of these communication systems produce chemical molecules that act n the body’s receptors to influence our behavior and emotions. The endocrine ystem, which secretes hormones into the bloodstream, delivers its messages much ıore slowly than the speedy nervous system, and the effects of the endocrine ystem’s messages tend to linger much longer than those of the nervous system.

Module 11 Studying the Brain, and Older Brain Structures

Page 101

Match the scanning technique with the correct description

1. fMRI scan

2. PET scan

3. MRI scan

a. tracks radioactive glucose to reveal brain *activity*.

b. tracks successive images of brain tissue to show brain *function*.

c. uses magnetic fields and radio waves to show brain *anatomy*.

ınswer: 1, b; 2, a; 3, c

Page 103

The _____________ is a crossover point where nerves from the left side of the brain are mostly linked to the right side of the body, and vice versa.

ınswer: brainstem

Page 107

What are the three key structures of the limbic system, and what functions do they serve?

ınswer: (1) The *amygdala* is involved in aggression and fear responses. (2) The *ypothalamus* is involved in bodily maintenance, pleasurable rewards, and control of ıe hormonal systems. (3) The *hippocampus* processes memory of facts and events.

Electrical stimulation of a cat’s amygdala provokes angry reactions. Which *autonomic nervous system* division is activated by such stimulation?

ınswer: The sympathetic nervous system

In what brain region would damage be most likely to (1) disrupt your ability to jump rope? (2) disrupt your ability to hear? (3) leave you in a coma? (4) cut off the very breath and heartbeat of life?

nswer: (1) cerebellum; (2) thalamus; (3) reticular formation; (4) medulla

Module 12 The Cerebral Cortex

Page 109

Which area of the human brain is most similar to that of less complex animals? Which part of the human brain distinguishes us most from less complex animals?

nswer: the brainstem; the cerebral cortex

Page 116

Our brain's ______________ cortex registers and processes body touch and movement sensations. The ______________ cortex controls our voluntary movements.

nswer: somatosensory; motor

Why are association areas important?

nswer: Association areas are involved in higher mental functions—interpreting, tegrating, and acting on information processed in other areas.

Page 118

Try moving your right hand in a circular motion, as if cleaning a table. Then start your right foot doing the same motion, synchronized with your hand. Now reverse the right foot's motion, but not the hand's. Finally, try moving the *left* foot opposite to the right hand.

1. **Why is reversing the right foot's motion so hard?**
2. **Why is it easier to move the left foot opposite to the right hand?**

nswer: 1. The right limbs' opposed activities interfere with each other because oth are controlled by the same (left) side of your brain. 2. Opposite sides of your rain control your left and right limbs, so the reversed motion causes less terference.

Module 13 Brain Hemisphere Organization and the Biology of Consciousness

Page 122

(1) If we flash a red light to the right hemisphere of a right-handed person with a split brain, and flash a green light to the left hemisphere, will each observe its own color? (2) Will the person be aware that the colors differ? (3) What will the person verbally report seeing?

nswer: (1) yes; (2) no; (3) green

Page 127

Those working in the interdisciplinary field called ______________ ______________ study the brain activity associated with the mental processes of perception, thinking, memory, and language.

nswer: cognitive neuroscience

What are the mind’s two tracks, and what is *dual processing?*

nswer: The human brain has separate conscious and unconscious tracks that
rocess information simultaneously. In vision, for example, the visual action track
ormally guides our conscious visual processing, while the visual perception track
ormally operates unconsciously, enabling our quick recognition of objects.

Module 14 Behavior Genetics: Predicting Individual Differences

Page 131

Put the following cell structures in order from smallest to largest: nucleus, gene, chromosome.

nswer: gene, chromosome, nucleus

Page 135

How do researchers use twin and adoption studies to learn about psychological principles?

nswer: Researchers use twin and adoption studies to understand how much
ariation among individuals is due to genetic makeup and how much is due to

nvironmental factors. Some studies compare the traits and behaviors of identical vins (same genes) and fraternal twins (different genes, as in any two siblings). hey also compare adopted children with their adoptive and biological parents. ome studies compare traits and behaviors of twins raised together or separately.

Page 136

Those studying the *heritability* of a trait try to determine how much of the person-to-person variation in that trait among members of a specific group is due to their differing _____________.

nswer: genes

Page 138

Match the following terms to the correct explanation.

1. Epigenetics	**a. Study of the relative effects of our genes and our environment on our behavior.**
2. Molecular behavior genetics	**b. Study of how the structure and function of specific genes interact with our environment to influence behavior.**
3. Behavior genetics	**c. Study of environmental factors that affect how our genes are expressed.**

nswer: 1, c; 2, b; 3, a

Module 15 Evolutionary Psychology: Understanding Human Nature

Page 142

How are Belyaev and Trut's fox-breeding practices similar to, and how do they differ from, the way natural selection normally occurs?

nswer: Over multiple generations, Belyaev and Trut selected and bred foxes that xhibited a trait they desired: tameness. This process is similar to naturally occurring lection, but it differs in that natural selection is much slower, and normally favors aits (including those arising from mutations) that contribute to reproduction and rvival.

Page 146

How do evolutionary psychologists explain male-female differences in sexuality?

nswer: Evolutionary psychologists theorize that females have inherited their ncestors’ tendencies to be more cautious sexually because of the challenges ssociated with incubating and nurturing offspring. Males have inherited a tendency be more casual about sex, because their act of fathering requires a smaller vestment.

What are the three main criticisms of the evolutionary explanation of human sexuality?

nswer: (1) It starts with an effect and works backward to propose an explanation.) This explanation may overlook the effects of cultural expectations and cialization. (3) Men could use such explanations to rationalize their irresponsible ehavior toward women.

Page 149

How does the biopsychosocial approach explain our individual development?

nswer: The biopsychosocial approach considers all the factors that influence our dividual development: biological factors (including evolution and our genes, ormones, and brain), psychological factors (including our experiences, beliefs, elings, and expectations), and social-cultural factors (including parental and peer fluences, cultural individualism or collectivism, and gender norms).

Unit IV

Sensation and Perception

Module 16 Basic Concepts of Sensation and Perception

Page 166

Explain how Heather Sellers' experience of prosopagnosia illustrates the difference between sensation and perception.

nswer: Heather Sellers' sensation is normal, and her perception is nearly so, but er brain is lacking the functional area that helps us recognize a familiar human ce. While her bottom-up physical sensory system receives and represents stimuli, a roblem with her top-down mental process of organizing and interpreting sensory put results in her inability to recognize faces.

Explain three attentional principles that magicians may use to fool us.

nswer: Our *selective attention* allows us to focus on only a limited portion of our rroundings. *Inattentional blindness* explains why we don't perceive some things hen we are distracted. And *change blindness* happens when we fail to notice a latively unimportant change in our environment. All these principles help agicians fool us, as they direct our attention elsewhere to perform their tricks.

Using sound as your example, explain how these concepts differ: *absolute threshold, subliminal stimulation,* and *difference threshold.*

nswer: *Absolute threshold* is the minimum stimulation needed to detect a articular sound (such as an approaching bike on the sidewalk behind you) 50 ercent of the time. *Subliminal* stimulation happens when, without your awareness, our sensory system processes a sound that is below your absolute threshold (such s when your perceptions are affected by first being primed by a subliminally heard ord). A *difference threshold* is the minimum sound difference a person can detect or example, when listening to music, how many times you need to increase the olume in order to notice the difference).

Why is it that after wearing shoes for a while, you cease to notice them?

nswer: The shoes provide constant stimulation. Thanks to *sensory adaptation,* we nd to focus primarily on changing stimuli.

Module 17 Influences on Perception

Page 174

What type of evidence shows that, indeed, "there is more to perception than

meets the senses"?

nswer: We construct our perceptions based on both sensory input and—xperiments show—on our assumptions, expectations, schemas, and perceptual sets, ften influenced by the surrounding context.

Does *perceptual set* involve bottom-up or top-down processing? Why?

nswer: It involves top-down processing, because it draws on your experiences, ssumptions, and expectations when interpreting stimuli.

If an ESP event occurred under controlled conditions, what would be the next best step to confirm that ESP really exists?

nswer: The ESP event would need to be reproduced in other scientific studies.

Module 18 Vision: Sensory and Perceptual Processing

Page 180

Some nocturnal animals, such as toads, mice, rats, and bats, have impressive night vision thanks to having many more _____________ (rods/cones) than _____________ (rods/cones) in their retinas. These creatures probably have very poor _____________ (color/black-and-white) vision.

nswer: rods; cones; color

Cats are able to open their _____________ much wider than we can, which allows more light into their eyes so they can see better at night.

nswer: pupils

Page 182

What are two key theories of color vision? Are they contradictory or complementary? Explain.

nswer: The *Young-Helmholtz trichromatic theory* shows that the retina contains olor receptors for red, green, and blue. The *opponent-process theory* shows that we ave opponent-process cells in the retina and thalamus for red-green, blue-yellow, nd white-black. These theories are complementary and outline the two stages of olor vision: (1) The retina's receptors for red, green, and blue respond to different olor stimuli. (2) The receptors’ signals are then processed by the opponent-process ells on their way to the visual cortex in the brain.

Page 185

What is the rapid sequence of events that occurs when you see and recognize a friend?

nswer: Light waves reflect off the person and travel into your eyes. Receptor cells n your retina convert the light waves’ energy into millions of neural impulses sent o your brain. Your brain’s detector cells and work teams process the subdimensions f this visual input—including color, movement, form, and depth—separately but imultaneously. Your brain interprets this information, based on previously stored nformation and your expectations, and forms a conscious perception of your friend.

Module 19 Visual Organization and Interpretation

Page 195

In terms of perception, a band’s lead singer would be considered ______________ (figure/ground), and the other musicians would be considered ______________ (figure/ground).

nswer: figure; ground

What do we mean when we say that, in perception, “the whole may exceed the sum of its parts”?

nswer: Gestalt psychologists used this saying to describe our perceptual tendency o organize clusters of sensations into meaningful forms or coherent groups.

How do we normally perceive depth?

nswer: We are normally able to perceive depth thanks to (1) binocular cues (such s retinal disparity), and (2) monocular cues (which include relative height, relative ize, interposition, linear perspective, light and shadow, and relative motion).

Module 20 Hearing

Page 203

What are the basic steps in transforming sound waves into perceived sound?

nswer: The *outer ear* collects sound waves, which are translated into mechanical aves by the *middle ear* and turned into fluid waves in the *inner ear*. The *auditory erve* then translates the energy into electrical waves and sends them to the brain, hich perceives and interprets the sound.

The amplitude of a sound wave determines our perception of ____________ (loudness/pitch).

nswer: loudness

The longer the sound waves, the ____________ (lower/higher) their frequency and the ____________ (higher/lower) their pitch.

nswer: lower; lower

Which theory of pitch perception would best explain a symphony audience's enjoyment of a high-pitched piccolo? How about a low-pitched cello?

nswer: place theory; frequency theory

Module 21 The Other Senses

Page 216

Which of the following options has NOT been proven to reduce pain? a. Distraction b. Placebos c. Phantom limb sensations d. Endorphins

nswer: c

Where are the kinesthetic receptors and the vestibular sense receptors located?

nswer: Kinesthetic receptors are located in our joints, tendons, and muscles. estibular sense receptors are located in our inner ear.

Unit V

Consciousness and the Two-Track Mind

Module 22 Understanding Consciousness and Hypnosis

Page 228

When is hypnosis potentially harmful, and when can hypnosis be used to help?

nswer: Hypnosis can be harmful if used to “hypnotically refresh” memories, hich may plant false memories. But posthypnotic suggestions have helped alleviate ome ailments, and hypnosis can also help control pain.

Hilgard believed that hypnosis involves a state of divided consciousness called ______________. His beliefs have been challenged by researchers who suggest ______________ influence is involved.

nswer: dissociation; social

Module 23 Sleep Patterns and Sleep Theories

Page 236

What are the four sleep stages, and in what order do we normally travel through those stages?

nswer: NREM-1, NREM-2, NREM-3, REM; normally we move through NREM-, then NREM-2, then NREM-3, then back up through NREM-2 before we xperience REM sleep.

Can you match the cognitive experience with the sleep stage?

1. NREM-1 **a. story-like dream**

2. NREM-3 **b. fleeting images**

3. REM **c. minimal awareness**

nswer: 1, b; 2, c; 3, a

The ______________ nucleus helps monitor the brain’s release of melatonin, which affects our ______________ rhythm.

nswer: suprachiasmatic; circadian

Page 238

What are five proposed reasons for our need for sleep?

nswer: (1) Sleep has survival value. (2) Sleep helps us restore the immune system nd repair brain tissue. (3) During sleep we consolidate memories. (4) Sleep fuels reativity. (5) Sleep plays a role in the growth process.

Module 24 Sleep Deprivation, Sleep Disorders, and Dreams

Page 247

A well-rested person would be more likely to have ____________ (trouble concentrating/quick reaction times) and a sleep-deprived person would be more likely to ____________ (gain weight/fight off a cold).

nswer: quick reaction times; gain weight

Page 251

Are you getting enough sleep? What might you ask yourself to answer this question?

nswer: You could start with the true/false questions in James Maas’ sleep eprivation quiz in Table 24.1. Also, William Dement (1999, p. 73) has suggested onsidering these questions: “How often do you think about taking a quick snooze? low often do you rub your eyes and yawn during the day? How often do you feel ke you really need some coffee?” Dement concluded that “each of these is a arning of a sleep debt that you ignore at your peril.”

What five theories propose explanations for why we dream?

nswer: (1) Freud’s wish-fulfillment (dreams as a psychic safety valve), (2) nformation-processing (dreams sort the day’s events and consolidate memories), (3) hysiological function (dreams pave neural pathways), (4) activation-synthesis REM sleep triggers random neural activity that the mind weaves into stories), and 5) cognitive development (dreams reflect the dreamer’s developmental stage)

Module 25 Psychoactive Drugs

Page 255

What is the process that leads to drug tolerance?

nswer: With repeated exposure to a psychoactive drug, the user’s brain chemistry dapts and the drug’s effect lessens. Thus, it takes bigger doses to get the desired ffect.

Can someone become “addicted” to shopping?

nswer: Unless it becomes compulsive or dysfunctional, simply having a strong terest in shopping is not the same as having a physical addiction to a drug. It pically does not involve obsessive craving in spite of known negative onsequences.

Page 257

Alcohol, barbiturates, and opiates are all in a class of drugs called ______________.

nswer: depressants

Page 259

What withdrawal symptoms should your friend expect when she finally decides to quit smoking?

nswer: Nicotine-withdrawal symptoms include strong cravings, insomnia, anxiety, ritability, distractibility, and difficulty concentrating. However, if your friend icks with it, the craving and withdrawal symptoms will gradually dissipate over bout six months.

Page 264

Why do tobacco companies try so hard to get customers hooked as teens?

nswer: Nicotine is powerfully addictive, expensive, and deadly. Those who start aving the neural pathways when young may find it very hard to stop using nicotine. s a result, tobacco companies may have lifelong customers.

“How strange would appear to be this thing that men call pleasure! And how curiously it is related to what is thought to be its opposite, pain! . . . Wherever the one is found, the other follows up behind.” (Plato, *Phaedo,* fourth century B.C.E.) How does this pleasure-pain description apply to the repeated use of psychoactive drugs?

nswer: Psychoactive drugs create pleasure by altering brain chemistry. With peated use of the drug, the user develops tolerance and needs more of the drug to chieve the desired effect. (Marijuana is an exception.) Discontinuing use of the ubstance then produces painful or psychologically unpleasant withdrawal ymptoms.

Unit VI

Learning

Module 26 How We Learn and Classical Conditioning

Page 272

Why are habits, such as having something sweet with that cup of coffee, so hard to break? (Hint: Think about learned associations.)

nswer: Habits form when we repeat behaviors in a given context and, as a result, earn associations—often without our awareness. For example, we may have eaten a weet pastry with a cup of coffee often enough to associate the flavor of the coffee ith the treat, so that the cup of coffee alone just doesn't seem right anymore!

As we develop, we learn cues that lead us to expect and prepare for good and bad events. We learn to repeat behaviors that bring rewards. And we watch others and learn. What do psychologists call these three types of learning?

nswer: Through *classical conditioning*, we learn cues that lead us to expect and repare for good and bad events. Through *operant conditioning*, we learn to repeat ehaviors that bring rewards. Through *cognitive learning*, we watch others and earn.

Page 274

An experimenter sounds a tone just before delivering an air puff that causes your eye to blink. After several repetitions, you blink to the tone alone. What is the NS? The US? The UR? The CS? The CR?

nswer: NS = tone before conditioning; US = air puff; UR = blink to air puff; CS = ne after conditioning; CR = blink to tone

Page 276

If the aroma of a baking cake sets your mouth to watering, what is the US? The CS? The CR?

nswer: The cake (including its taste) is the US. The associated aroma is the CS. alivation to the aroma is the CR.

The first step of classical conditioning, when an NS becomes a CS, is called _____________. When a US no longer follows the CS, and the CR becomes weakened, this is called _____________.

nswer: acquisition, extinction

Page 278

In horror movies, sexually arousing images of women are sometimes paired with violence against women. Based on classical conditioning principles, what might be an effect of this pairing?

nswer: If viewing an attractive nude or seminude woman (a US) elicits sexual rousal (a UR), then pairing the US with a new NS (violence) could turn the iolence into a conditioned stimulus (CS) that also becomes sexually arousing, a onditioned response (CR).

Module 27 Operant Conditioning

Page 283

With classical conditioning, we learn associations between events we _____________ (do/do not) control. With operant conditioning, we learn associations between our behavior and _____________ (resulting/random) events.

nswer: do not; resulting

Page 289

People who send spam e-mail are reinforced by which schedule? Home bakers checking the oven to see if the cookies are done are on which schedule? Sandwich shops that offer a free sandwich after every 10 sandwiches purchased are using which reinforcement schedule?

nswer: Spammers are reinforced on a variable-ratio schedule (after sending a arying number of e-mails). Cookie checkers are reinforced on a fixed-interval chedule. Sandwich shop programs use a fixed-ratio schedule.

Page 291

Fill in the three blanks below with one of the following terms: positive reinforcement (PR), negative reinforcement (NR), positive punishment (PP), and negative punishment (NP). We have provided the first answer (PR) for you.

Type of Stimulus	Give It	Take It Away
Desired (for example, a teen's use of the car):	1. PR	2.
Undesired/aversive (for example, an insult):	3.	4.

nswer: 1. PR (positive reinforcement); 2. NP (negative punishment); 3. PP ositive punishment); 4. NR (negative reinforcement)

Module 28 Operant Conditioning's Applications, and Comparison to Classical Conditioning

Page 297

Ethan constantly misbehaves at preschool even though his teacher scolds him repeatedly. Why does Ethan's misbehavior continue, and what can his teacher do to stop it?

nswer: If Ethan is seeking attention, the teacher's scolding may be reinforcing ther than punishing. To change Ethan's behavior, his teacher could offer einforcement (such as praise) each time he behaves well. The teacher might ncourage Ethan toward increasingly appropriate behavior through shaping, or by ephrasing rules as rewards instead of punishments. ("You can have a snack if you lay nicely with the other children" [reward] rather than "You will not get a snack if ou misbehave!" [punishment].)

Page 297

Salivating in response to a tone paired with food is a(n) ______________

behavior; pressing a bar to obtain food is a(n) _____________ behavior.

nswer: respondent *(classically conditioned);* operant

Module 29 Biology, Cognition, and Learning

Page 302

How did Garcia and Koelling’s taste-aversion studies help disprove Gregory Kimble’s early claim that “just about any activity of which the organism is capable can be conditioned . . . to any stimulus that the organism can perceive”?

nswer: Garcia and Koelling demonstrated that rats may learn an aversion to tastes, n which their survival depends, but not to sights or sounds.

Page 306

Instinctive drift and latent learning are examples of what important idea?

nswer: The success of operant conditioning is affected not just by environmental ues, but also by biological and cognitive factors.

Page 310

To cope with stress when we feel in control of our world, we tend to use _____________-focused (emotion/problem) strategies. To cope with stress when we believe we cannot change a situation, we tend to use _____________-focused (emotion/problem) strategies.

nswer: problem; emotion

Module 30 Observational Learning

Page 318

Jason’s parents and older friends all drive over the speed limit, but they advise him not to. Juan’s parents and friends drive within the speed limit, but they say nothing to deter him from speeding. Will Jason or Juan be more likely to speed?

nswer: Jason may be more likely to speed. Observational learning studies suggest at children tend to do as others do and say what they say.

Match the examples (1–5) to the appropriate underlying learning principle (a–e):

a. Classical conditioning	**1. Knowing the way from your bed to the bathroom in the dark**
b. Operant conditioning	**2. Your little brother getting in a fight after watching a violent action movie**
c. Latent learning	**3. Salivating when you smell brownies in the oven**
d. Observational learning	**4. Disliking the taste of chili after becoming violently sick a few hours after eating chili**
e. Biological predispositions	**5. Your dog racing to greet you on your arrival home**

nswer: 1, c; 2, d; 3, a; 4, e; 5, b

Unit VII

Cognition

Module 31 Studying and Encoding Memories

Page 328

Multiple-choice questions test our ______________. Fill-in-the-blank questions test our ______________.

nswer: recognition; recall

If you want to be sure to remember what you're learning for an upcoming test, would it be better to use *recall* or *recognition* to check your memory? Why?

nswer: It would be better to test your memory with *recall* (such as with short-nswer or fill-in-the-blank self-test questions) rather than *recognition* (such as with ultiple-choice questions). Recalling information is harder than recognizing it. So if ou can recall it, that means your retention of the material is better—and so are the dds of your later recognizing the correct answer. Your chances of test success are erefore greater.

Page 330

Memory includes (in alphabetical order) long-term memory, sensory memory, and working/short-term memory. What's the correct order of these in the three-stage memory model?

nswer: sensory memory, working/short-term memory, long-term memory

How does the working memory **concept update the classic Atkinson-Shiffrin three-stage information-processing model?**

nswer: The newer idea of a *working memory* emphasizes the active processing at we now know takes place in Atkinson-Shiffrin's short-term memory stage. hile the Atkinson-Shiffrin model viewed short-term memory as a temporary olding space, working memory plays a key role in processing new information and onnecting it to previously stored information.

What are two basic functions of working memory?

nswer: (1) Active processing of incoming visual and auditory information, and (2) cusing our spotlight of attention.

Page 335

What is the difference between *automatic* and *effortful* processing, and what are some examples of each?

nswer: *Automatic* processing occurs unconsciously (automatically) for such things s the sequence and frequency of a day's events, and reading and comprehending ords in our own language(s). *Effortful* processing requires attention and awareness nd happens, for example, when we work hard to learn new material in class, or new nes for a play.

At which of Atkinson-Shiffrin's three memory stages would *iconic* and *echoic* memory occur?

nswer: sensory memory

Page 337

What would be the most effective strategy to learn and retain a list of names of key historical figures for a week? For a year?

nswer: For a week: Make the names personally meaningful. For a year: Take dvantage of the spacing effect by spreading your learning over several months.

If you try to make the material you are learning personally meaningful, are you processing at a shallow or a deep level? Which level leads to greater retention?

nswer: Making material personally meaningful involves processing at a deep vel, because you are processing *semantically*—based on the meaning of the words. eep processing leads to greater retention.

Module 32 Storing and Retrieving Memories

Page 344

Which parts of the brain are important for implicit memory processing, and which parts play a key role in explicit memo**ry processing?**

nswer: The cerebellum and basal ganglia are important for *implicit* memory rocessing, and the frontal lobes and hippocampus are key to *explicit* memory rocessing.

Your friend has experienced brain damage in an accident. He can remember how to tie his shoes but has a hard time remembering anything you tell him during a conversation. How can implicit versus explicit information processing explain what’s going on here?

nswer: Our *explicit* conscious memories of facts and episodes differ from our *nplicit* memories of skills (such as tying shoelaces) and classically conditioned sponses. The parts of the brain involved in explicit memory processing (the frontal bes and hippocampus) may have sustained damage in the accident, while the parts volved in implicit memory processing (the cerebellum and basal ganglia) appear to ave escaped harm.

Which brain area responds to stress hormones by helping to create stronger

memories?

nswer: amygdala

Increased efficiency at the synapses is evidence of the neural basis of learning and memory. This is called ______________-______________ ______________.

nswer: long-term potentiation

Page 347

You have just watched a movie that includes a chocolate factory. After the chocolate factory is out of mind, you nevertheless feel a strange urge for a chocolate bar. How do you explain this in terms of priming?

nswer: Priming is the activation (often without our awareness) of associations. eeing a chocolate factory in a movie, for example, might temporarily predispose ou to crave a chocolate treat. Although you might not consciously remember the hocolate factory, it may prime how you interpret or recall events.

When we are tested immediately after viewing a list of words, we tend to recall the first and last items best, which is known as the ______________ ______________ effect.

nswer: serial position

Module 33 Forgetting, Memory Construction, and Improving Memory

Page 356

What are three ways we forget, and how does each of these happen?

nswer: (1) *Encoding failure:* Unattended information never entered our memory ystem. (2) *Storage decay:* Information fades from our memory. (3) *Retrieval ilure:* We cannot access stored information accurately, sometimes due to terference or motivated forgetting.

You will experience less ______________ (proactive/retroactive) interference if you learn new material in the hour before sleep than you will if you learn it before turning to another subject.

nswer: retroactive

Freud believed that we _____________ unacceptable memories to minimize anxiety.

nswer: repress

Page 361

What—given the commonness of source amnesia—might life be like if we remembered all our waking experiences and all our dreams?

nswer: Real experiences would be confused with those we dreamed. When seeing omeone we know, we might therefore be unsure whether we were reacting to omething they previously did or to something we dreamed they did.

Imagine being a jury member in a trial for a parent accused of sexual abuse based on a recovered memory. What insights from memory research should you offer the jury?

nswer: It will be important to remember the key points agreed upon by most esearchers and professional associations: Sexual abuse, injustice, forgetting, and emory construction all happen; recovered memories are common; memories from ur first four years are unreliable; memories claimed to be recovered through ypnosis are especially unreliable; and memories, whether real or false, can be motionally upsetting.

Page 363

What memory strategies can help you study smarter and retain more information?

nswer: Spend more time rehearsing or actively thinking about the material to oost long-term recall. Schedule spaced (not crammed) study times. Make the aterial personally meaningful, with well-organized and vivid associations. Refresh our memory by returning to contexts and moods that activate retrieval cues. Use nemonic devices. Minimize interference. Plan for a complete night’s sleep. Test ourself repeatedly—retrieval practice is a proven retention strategy.

Module 34 Thinking, Concepts, and Creativity

Page 368

According to Robert Sternberg, what are the five components of creativity?

nswer: Sternberg identified expertise, imaginative thinking skills, a venturesome ersonality, intrinsic motivation, and a creative environment as the five components f creativity.

Module 35 Solving Problems and Making Decisions

Page 379

Why is news so often focused on “something that hardly ever happens”? How does knowing this help us assess our fears?

nswer: If a tragic event such as a plane crash makes the news, it is noteworthy and nusual, unlike much more common bad events, such as traffic accidents. Knowing is, we can worry less about unlikely events and think more about improving the fety of our everyday activities. (For example, we can wear a seat belt when in a ehicle and use the crosswalk when walking.)

Match the process or strategy listed below (1–10) with its description (a–j).

1. Algorithm

2. Intuition

3. Insight

4. Heuristic

5. Fixation

a. Inability to view problems from a new angle; focuses thinking but hinders creative problem solving.

b. Methodological rule or procedure that guarantees a solution but requires time and effort.

c. Your fast, automatic, effortless feelings and thoughts based on your experience; huge and adaptive but can lead you to overfeel and underthink.

d. Simple thinking shortcut that enables quick and efficient decisions but puts us at risk for errors.

e. Sudden Aha! reaction that instantly

	reveals the solution.
6. Confirmation bias	**f. Tendency to search for support for your own views and to ignore contradictory evidence.**
7. Overconfidence	**g. Holding on to your beliefs even after they are proven wrong; closing your mind to new ideas.**
8. Creativity	**h. Overestimating the accuracy of your beliefs and judgments; allows you to be happier and to make decisions more easily, but puts you at risk for errors.**
9. Framing	**i. Wording a question or statement so that it evokes a desired response; can mislead people and influence their decisions.**
10. Belief perseverance	**j. The ability to produce novel and valuable ideas.**

nswer: 1, b; 2, c; 3, e; 4, d; 5, a; 6, f; 7, h; 8, j; 9, i; 10, g

Module 36 Thinking and Language

Page 382

How many morphemes are in the word *cuts*? How many phonemes?

nswer: two morphemes—*cut* and *s*, and four phonemes—*c*, *u*, *t*, and *s*

Page 387

What was the premise of researcher Noam Chomsky's work in language development?

nswer: Chomsky took the nature side of this discussion, when most other esearchers have emphasized the influence of nurture in language development. homsky maintained that all languages share a universal grammar, and humans are iologically predisposed to learn the grammar rules of language.

Why is it so difficult to learn a new language in adulthood?

nswer: Our brain’s *critical period* for language learning is in childhood, when we an absorb language structure almost effortlessly. As we move past that stage in our rain’s development, our ability to learn a new language diminishes dramatically.

What is the difference between *receptive* and *productive* language, and when do children normally hit these milestones in language development?

nswer: Infants normally start developing *receptive language* skills (ability to nderstand what is said to and about them) around 4 months of age. Then, starting ith babbling at 4 months and beyond, infants normally start building *productive nguage* skills (ability to produce sounds and eventually words).

Page 389

If children are not yet speaking, is there any reason to think they would benefit from parents and other caregivers reading to them?

nswer: Indeed there is, because well before age 1 children are learning to detect ords among the stream of spoken sounds and to discern grammatical rules. Before ge 1, they also are babbling with the phonemes of their own language. More than any parents realize, their infants are soaking up language. As researcher Peter sczyk reminds us, “Little ears are listening.”

______________ ______________ is one part of the brain that, if damaged, might impair your ability to speak words. Damage to ______________ ______________ might impair your ability to understand language.

nswer: Broca’s area; Wernicke’s area

Page 392

To say that “words are the mother of ideas” assumes the truth of what concept?

nswer: This phrase supports the linguistic determinism hypothesis, which asserts at language determines thought. Research indicates that this position is too xtreme, but—as linguistic influence suggests—language does influence what we erceive and think.

What is mental practice, and how can it help you to prepare for an upcoming event?

nswer: Mental practice uses visual imagery to mentally rehearse future behaviors, ctivating some of the same brain areas used during the actual behaviors. isualizing the details of the process is more effective than visualizing only your nd goal.

Unit VIII

Motivation, Emotion, and Stress

Module 37 Motivational Concepts

Page 404

Performance peaks at lower levels of arousal for difficult tasks, and at higher levels for easy or well-learned tasks. (1) How might this phenomenon affect marathon runners? (2) How might this phenomenon affect anxious test-takers facing a difficult test?

nswer: (1) Well-practiced runners tend to excel when aroused by competition. (2) igh anxiety about a difficult test may disrupt test-takers’ performance.

Page 406

An older friend recounted his weekend experience. After hours of driving to visit a friend he could not find anywhere to stop. Finally, he spotted a dimly lit diner. Although it looked deserted and a little creepy, he went in anyway because he was *really* hungry and thirsty. How would Maslow’s hierarchy of needs explain his behavior?

nswer: According to Maslow, the friend’s belongingness needs motivated the trip. is physiological needs of hunger and thirst took priority over his safety needs, rompting him to take a risk and enter the uninviting diner.

Module 38 Hunger Motivation

Page 411

Hunger occurs in response to _____________ (low/high) blood glucose and _____________ (low/high) levels of ghrelin.

nswer: low; high

Page 416

Why can two people of the same height, age, and activity level maintain the same weight, even if one of them eats much less than the other does?

nswer: Genetically influenced set/settling points, metabolism, and other factors fluence the way our bodies burn calories. Sleep deprivation, which makes us more ulnerable to weight gain, may also factor in.

You skipped lunch to meet with your guidance counselor, so you haven’t eaten anything in eight hours. As your long-awaited favorite dish is placed in front of you, your mouth waters in anticipation. Why?

nswer: You have learned to respond to the sight and aroma that signal the food bout to enter your mouth. Both *physiological* cues (low blood sugar) and *sychological* cues (anticipation of the tasty meal) heighten your experienced unger.

Module 39 Sexual Motivation

Page 421

The primary male sex hormone is _____________. The primary female sex hormones are the _____________.

nswer: testosterone; estrogens

What factors influence our sexual motivation and behavior?

nswer: Influences include biological factors such as sexual maturity and sex ormones, psychological factors such as environmental stimuli and fantasies, and ocial-cultural factors such as the values and expectations absorbed from family and e surrounding culture.

How might the drive-reduction theory and arousal theory explain our sexual

motivation?

nswer: *Drive-reduction theory:* Hormonal influences create a driven hysiologically aroused) state that compels us to reduce the drive. *Arousal theory:* eople sometimes *seek* the pleasure and stimulation of arousal.

Module 40 Affiliation and Achievement

Page 428

How have students reacted in studies where they were made to feel rejected and unwanted? What helps explain these results?

nswer: They engaged in more self-defeating behaviors and displayed more isparaging and aggressive behavior. These students' basic *need to belong* seems to ave been disrupted.

Social networking tends to _____________ (strengthen/weaken) your relationships with people you already know and _____________ (increase/decrease) your self-disclosure.

nswer: strengthen; increase

Page 430

What have researchers found to be an even better predictor of school performance than intelligence test scores?

nswer: self-discipline (*grit*)

How might drive-reduction theory and arousal theory explain our affiliation and achievement needs?

nswer: *Drive-reduction theory:* Being threatened and afraid drives us to find fety in the company of others (thus reducing our aroused state). *Arousal theory:* e welcome optimal levels of arousal, and the presence of others is arousing.

Module 41 Theories and Physiology of Emotion

Page 436

According to the Cannon-Bard theory, (a) our *physiological response* to a stimulus (for example, a pounding heart), and (b) the *emotion* we experience

(for example, fear) occur _____________ (simultaneously/sequentially). According to the James-Lange theory, (a) and (b) occur _____________ (simultaneously/sequentially).

nswer: simultaneously; sequentially (first the physiological response, and then the xperienced emotion)

According to Schachter and Singer, two factors lead to our experience of an emotion: (1) physiological arousal and (2) _____________ appraisal.

nswer: cognitive

Emotion researchers have disagreed about whether emotional responses occur in the absence of cognitive processing. How would you characterize the approach of each of the following researchers: Zajonc, LeDoux, Lazarus, Schachter, and Singer?

nswer: Zajonc and LeDoux suggested that we experience some emotions without ny conscious, cognitive appraisal. Lazarus, Schachter, and Singer emphasized the nportance of appraisal and cognitive labeling in our experience of emotion.

Page 440

How do the two divisions of the autonomic nervous system affect our emotional responses?

nswer: The *sympathetic division* of the ANS arouses us for more intense xperiences of emotion, pumping out the stress hormones epinephrine and orepinephrine to prepare our body for fight or flight. The *parasympathetic division* f the ANS takes over when a crisis passes, restoring our body to a calm hysiological and emotional state.

Module 42 Expressing Emotion

Page 448

_____________ (Women/Men) report experiencing emotions more deeply, and they tend to be more adept at reading nonverbal behavior.

nswer: Women

Are people more likely to differ culturally in their interpretations of facial expressions, or of gestures?

nswer: gestures

Module 43 Stress and Illness

Page 455

The stress response system: When alerted to a negative, uncontrollable event, our _____________ nervous system arouses us. Heart rate and respiration _____________ (increase/decrease). Blood is diverted from digestion to the skeletal _____________. The body releases sugar and fat. All this prepares the body for the _____________ – _____________ – _____________response.

nswer: sympathetic; increase; muscles; fight-or-flight

Page 458

The field of _____________ studies mind-body interactions, including the effects of psychological, neural, and endocrine functioning on the immune system and overall health.

nswer: psychoneuroimmunology

What general effect does stress have on our health?

nswer: Stress tends to reduce our immune system’s ability to function properly, so at higher stress generally leads to greater risk of physical illness.

Page 462

Which component of the Type A personality has been linked most closely to coronary heart disease?

nswer: feeling angry and negative much of the time

Module 44 Health and Happiness

Page 472

What are some of the tactics we can use to successfully manage the stress we cannot avoid?

nswer: aerobic exercise, relaxation procedures, mindfulness meditation, and eligious engagement

Page 478

Which of the following factors does NOT predict self-reported happiness?

- **a. Age**
- **b. Personality traits**
- **c. Sleep and exercise**
- **d. Active religious faith**
- **e. Engaging work and leisure**

nswer: Age does NOT effectively predict happiness levels. Better predictors are ersonality traits, sleep and exercise, religious faith, and engaging work and leisure.

Unit IX

Developmental Psychology

Module 45 Developmental Issues, Prenatal Development, and the Newborn

Page 488

Developmental researchers who emphasize learning and experience are supporting ______________; those who emphasize biological maturation are supporting ______________.

nswer: continuity; stages

What findings in psychology support (1) the stage theory of development and (2) the idea of stability in personality across the life span?

nswer: (1) Stage theory is supported by the work of Piaget (cognitive evelopment), Kohlberg (moral development), and Erikson (psychosocial evelopment). (2) Some traits, such as temperament, exhibit remarkable stability cross many years. But we do change in other ways, such as in our social attitudes.

Page 492

The first two weeks of prenatal development is the period of the _____________. The period of the _____________ lasts from 9 weeks after conception until birth. The time between those two prenatal periods is considered the period of the _____________.

nswer: zygote; fetus; embryo

Your friend’s older sister—a regular drinker—hopes to become pregnant soon and has stopped drinking. Why is this a good idea? What negative effects might alcohol consumed during pregnancy have on a developing fetus?

nswer: There is no known safe amount of alcohol during pregnancy, so your iend’s older sister is wise to quit drinking before becoming pregnant. Harmful ffects may occur even before a woman knows she is pregnant. If a woman drinks ersistently and heavily during her pregnancy, the fetus will be at risk for severe hysical and cognitive impairments (such as occurs with fetal alcohol syndrome).

Infants’ _____________ to repeated stimulation helps developmental psychologists study what they can learn and remember.

nswer: habituation

Module 46 Infancy and Childhood: Physical Development

Page 496

What is the biological growth process that explains why most children begin walking by about 12 to 15 months?

nswer: maturation

Module 47 Infancy and Childhood: Cognitive Development

Page 504

Match the correct cognitive developmental stage (a–d) to each developmental phenomenon (1–6).

a. Sensorimotor **1. Thinking about abstract concepts, such as “freedom.”**

b. Preoperational **2. Enjoying imaginary play (such as**

	dress-up).
c. Concrete operational	**3. Understanding that physical properties stay the same even when objects change form.**
d. Formal operational	**4. Having the ability to reverse math operations.**
	5. Understanding that something is not gone for good when it disappears from sight, as when Mom “disappears” behind the shower curtain.
	6. Having difficulty taking another’s point of view (as when blocking someone’s view of the TV).

nswer: 1, d; 2, b; 3, c; 4, c; 5, a; 6, b

Page 507

Use Piaget’s first three stages of cognitive development to explain why children are not just miniature adults in the way they think.

nswer: Infants in the sensorimotor stage tend to be focused only on their own erceptions of the world and may, for example, be unaware that objects continue to xist when unseen. A preoperational child is still egocentric and incapable of ppreciating simple logic, such as the reversibility of operations. A preteen in the oncrete operational stage is beginning to think logically about concrete events but ot about abstract concepts.

What does *theory of mind* have to do with autism spectrum disorder?

nswer: Theory of mind focuses on our ability to understand our own and others’ ental states. Those with autism spectrum disorder struggle with this ability.

Module 48 Infancy and Childhood: Social Development

Page 516

The four parenting styles may be described as “too hard, too soft, too uncaring, and just right.” Which parenting style goes with each of these descriptions, and how do children benefit from the “just right” style?

nswer: The authoritarian style would be described as too hard, the permissive tyle too soft, the negligent style too uncaring, and the authoritative style just right. arents using the authoritative style tend to have children with high self-esteem, elf-reliance, self-regulation, and social competence.

Page 518

What distinguishes imprinting from attachment?

nswer: Attachment is the normal process by which we form emotional ties with nportant others. Imprinting occurs only in certain animals that have a critical eriod very early in their development during which they must form their ttachments, and they do so in an inflexible manner.

Module 49 Gender Development

Page 524

______________ (Men/Women) are more likely to commit relational aggression, and ______________ (men/women) are more likely to commit physical aggression.

nswer: Women; men

Page 527

What are gender roles, and what do their variations tell us about our human capacity for learning and adaptation?

nswer: *Gender roles* are social rules or norms for accepted and expected female nd male behaviors. The norms associated with various roles, including gender les, vary widely in different cultural contexts, which is proof that we are able to earn and adapt to the social demands of different environments.

Module 50 Parents, Peers, and Early Experiences

Page 532

To predict whether a teenager smokes, ask how many of the teen’s friends smoke. One explanation for this correlation is peer influence. What’s another?

nswer: There may also be a *selection effect.* Adolescents tend to select similar thers and sort themselves into like-minded groups. Those who smoke may seek out ther teenagers who also smoke.

Module 51 Adolescence: Physical and Cognitive Development

Page 537

According to Kohlberg, _____________ morality focuses on self-interest, _____________ morality focuses on self-defined ethical principles, and _____________ morality focuses on upholding laws and social rules.

nswer: preconventional; postconventional; conventional

How has Kohlberg’s theory of moral reasoning been criticized?

nswer: Kohlberg’s work reflected an individualist worldview, so his theory is less ulturally universal than he supposed.

Module 52 Adolescence: Social Development and Emerging Adulthood

Page 543

How has the transition from childhood to adulthood changed in Western cultures in the last century or so?

nswer: In little more than a century, the gap between puberty and adult ndependence has widened from about 7 years to about 14 years. This longer dolescence gives us a chance to grow up a bit more before facing the “real world,” ut it also comes with its share of stressors, as sexually mature teens must wait many ears before achieving true independence. In Western nations, this has led to a ostadolescent, not-yet-settled phase of life known as *emerging adulthood.*

Match the psychosocial development stage (1–8) with the issue that Erikson believed we wrestle with at that stage (a–h).

1. Infancy	**a. Generativity vs. stagnation**

2. Toddlerhood

3. Preschool

4. Elementary school

5. Adolescence

6. Young adulthood

7. Middle adulthood

8. Late adulthood

b. Integrity vs. despair

c. Initiative vs. guilt

d. Intimacy vs. isolation

e. Identity vs. role confusion

f. Competence vs. inferiority

g. Trust vs. mistrust

h. Autonomy vs. shame and doubt

nswer: 1, g; 2, h; 3, c; 4, f; 5, e; 6, d; 7, a; 8, b

Module 53 Sexual Development

Page 549

Prenatal sexual development begins about _____________ weeks after conception. Adolescence is marked by the onset of _____________.

nswer: seven; puberty

From a biological perspective, HIV is passed more readily from women to men than from men to women. True or false?

nswer: False. HIV is transmitted more easily and more often from men to women.

Which THREE of the following five factors contribute to unplanned teen pregnancies?

a. Alcohol use
b. Higher intelligence level
c. Father absence
d. Mass media models
e. Participating in service learning programs

nswer: a, c, d

Page 556

Which THREE of the following five factors have researchers found to have an effect on sexual orientation?

a. A domineering mother
b. The size of a certain cell cluster in the hypothalamus
c. Prenatal hormone exposure
d. A distant or ineffectual father
e. For right-handed men, having multiple older biological brothers

nswer: b, c, e

Module 54 Adulthood: Physical, Cognitive, and Social Development

Page 569

Freud defined the healthy adult as one who is able to _____________ and to _____________.

nswer: love; work

What are some of the most significant challenges and rewards of growing old?

nswer: Challenges: decline of muscular strength, reaction times, stamina, sensory eenness, cardiac output, and immune system functioning. Risk of cognitive decline ncreases. Rewards: positive feelings tend to grow; negative emotions are less ntense; and anger, stress, worry, and social-relationship problems decrease.

Research has shown that living together before marriage predicts an increased likelihood of future divorce. What are some possible explanations for this correlation?

nswer: First, those who choose to live together are often less committed to the nduring marriage ideal. Second, they may become even less supportive of this ideal hile cohabiting. Third, people may be more reluctant to break up with a cohabiting artner than a dating partner, despite suspecting that the relationship is nsustainable.

Unit X

Personality

Module 55 Psychoanalytic and Psychodynamic Theories

Page 582

According to Freud's ideas about the three-part personality structure, the _____________ operates on the *reality principle* and tries to balance demands in a way that produces long-term pleasure rather than pain, the _____________ operates on the *pleasure principle* and seeks immediate gratification, and the _____________ represents the voice of our internalized ideals (our *conscience*).

nswer: ego; id; superego

In the psychoanalytic view, conflicts unresolved during one of the psychosexual stages may lead to _____________ at that stage.

nswer: fixation

Freud believed that our defense mechanisms operate _____________ (consciously/unconsciously) and defend us against _____________.

nswer: unconsciously; anxiety

Page 588

What are three big ideas that have survived from Freud's psychoanalytic theory? What are three ways in which Freud's theory has been criticized?

nswer: Freud is credited with first drawing attention to (1) the importance of
hildhood experiences, (2) the existence of the unconscious mind, and (3) our self-
rotective defense mechanisms. Freud's theory has been criticized as (1) not
cientifically testable and offering after-the-fact explanations, (2) focusing too much
n sexual conflicts in childhood, and (3) being based on the idea of repression,
hich has not been supported by modern research.

Which elements of traditional psychoanalysis have modern-day psychodynamic theorists and therapists retained, and which elements have they mostly left behind?

nswer: Today's psychodynamic theorists and therapists still rely on the
nterviewing techniques that Freud used, and they still tend to focus on childhood

xperiences and attachments, unresolved conflicts, and unconscious influences. owever, they are not likely to dwell on fixation at any psychosexual stage, or the ea that sexual issues are the basis of our personality.

Module 56 Humanistic Theories

Page 594

How did humanistic psychology provide a fresh perspective?

nswer: The humanistic theories sought to turn psychology’s attention away from rives and conflicts and toward our growth potential. This movement’s focus on the ay people strive for self-determination and self-realization was in contrast to reudian theory and strict behaviorism.

What does it mean to be empathic? How about self-actualized? Which humanistic psychologists used these terms?

nswer: To be *empathic* is to share and mirror another person’s feelings. Carl ogers believed that people nurture growth in others by being empathic. Abraham aslow proposed that *self-actualization* is the motivation to fulfill one’s potential, nd one of the ultimate psychological needs (the other is self-transcendence).

Module 57 Trait Theories

Page 601

Which two primary dimensions did Hans Eysenck and Sybil Eysenck propose for describing personality variation?

nswer: introversion–extraversion and emotional stability–instability

What are the Big Five personality factors, and why are they scientifically useful?

nswer: The Big Five personality factors are *c*onscientiousness, *a*greeableness, euroticism (emotional stability vs. instability), *o*penness, and *e*xtraversion: ANOE. These factors may be objectively measured, they are relatively stable over e life span, and they apply to all cultures in which they have been studied.

Page 604

How well do personality test scores predict our behavior? Explain.

nswer: Our scores on personality tests predict our *average* behavior across many ituations much better than they predict our specific behavior in any given situation.

Module 58 Social-Cognitive Theories

Page 609

Albert Bandura proposed the _____________-_____________ perspective on personality, which emphasizes the interaction of people with their environment. To describe the interacting influences of behavior, thoughts, and environment, he used the term _____________ _____________.

nswer: social-cognitive; reciprocal determinism

What is the best way to predict a person's future behavior?

nswer: Examine the person's past behavior patterns in similar situations.

Module 59 Exploring the Self

Page 616

What are the positive and negative effects of high self-esteem?

nswer: People who feel confident in their abilities are often happier, have greater otivation, and are less susceptible to depression. Inflated self-esteem can lead to elf-serving bias, greater aggression, and narcissism.

The tendency to accept responsibility for success and blame circumstances or bad luck for failure is called _____________ – _____________ _____________ .

nswer: self-serving bias

_____________ (Secure/Defensive) self-esteem is linked to angry and aggressive behavior. _____________ (Secure/Defensive) self-esteem is a healthier self-image that allows us to focus beyond ourselves and enjoy a higher quality of life.

nswer: Defensive; Secure

Page 618

How do people in individualist and collectivist cultures differ?

nswer: Individualists give priority to personal goals over group goals and tend to efine their identity in terms of their own personal attributes. Collectivists give riority to group goals over individual goals and tend to define their identity in terms f group identifications.

Unit XI

Testing and Individual Differences

Module 60 Introduction to Intelligence

Page 630

How does the existence of savant syndrome support Gardner’s theory of multiple intelligences?

nswer: People with savant syndrome have limited mental ability overall but ossess one or more exceptional skills. According to Howard Gardner, this suggests at our abilities come in separate packages rather than being fully expressed by one eneral intelligence that encompasses all our talents.

Joseph, a Harvard Law School student, has a straight-A average, writes for the *Harvard Law Review,* and will clerk for a Supreme Court justice next year. His grandmother, Judith, is very proud of him, saying he is far more intelligent than she ever was. But Joseph is also very proud of Judith: As a young woman, she was imprisoned by the Nazis. When the war ended, she walked out of Germany, contacted an agency helping refugees, and began a new life in the United States as an assistant chef in her cousin’s restaurant. According to the definition of intelligence in this unit, is Joseph the only intelligent person in this story? Why or why not?

nswer: Joseph is not the only intelligent person in this story. Intelligence is the bility to learn from experience, solve problems, and use knowledge to adapt to new tuations. Judith certainly demonstrates this quality as well, given all that she has ccomplished.

Module 61 Assessing Intelligence

Page 634

What did Binet hope to achieve by establishing a child's mental age?

nswer: Binet hoped that determining the child's mental age (the age that typically orresponds to a certain level of performance) would help identify appropriate chool placements.

What is the IQ of a 4-year-old with a mental age of 5?

nswer: 125 (5 ÷ 4 × 100 = 125)

Page 638

An employer with a pool of applicants for a single available position is interested in testing each applicant's potential. To determine that, she should use an _____________ (achievement/aptitude) test. That same employer wishing to test the effectiveness of a new, on-the-job training program would be wise to use an _____________ (achievement/aptitude) test.

nswer: aptitude; achievement

What are the three criteria that a psychological test must meet in order to be widely accepted? Explain.

nswer: A psychological test must be *standardized* (pretested on a representative ample of people), *reliable* (yielding consistent results), and *valid* (measuring and redicting what it is supposed to).

Correlation coefficients were used in this section. Here's a quick review: Correlations do not indicate cause-effect, but they do tell us whether two things are associated in some way. A correlation of -1.00 represents perfect _____________ (agreement/disagreement) between two sets of scores: As one score goes up, the other score goes _____________ (up/down). A correlation of _____________ represents no association. The highest correlation, +1.00, represents perfect _____________ (agreement/disagreement): As the first score goes up, the other score goes _____________ (up/down).

nswer: disagreement; down; zero; agreement; up

Module 62 The Dynamics of Intelligence

Page 645

Researcher A is well-funded to learn about how intelligence changes over the life span. Researcher B wants to study the intelligence of people who are now at various life stages. Which researcher should use the cross-sectional method, and which the longitudinal method?

nswer: Researcher A should develop a *longitudinal study* to examine how
telligence changes in the same people over the life span. Researcher B should
evelop a *cross-sectional study* to examine the intelligence of people now at various
fe stages.

Why do psychologists not diagnose an intellectual disability based solely on a person's intelligence test score?

nswer: An intelligence test score is only one measure of a person's ability to
nction. Other important factors to consider in an overall assessment include
onceptual skills, social skills, and practical skills.

The Smiths have enrolled their 2-year-old son in a special program that promises to assess his IQ and, if he places in the top 5 percent of test-takers, to create a plan that will guarantee his admission to a top university at age 18. Why is this endeavor of questionable value?

nswer: First, IQ tests given before age 3 are only modestly reliable predictors of
dult intelligence. Second, admission to a top university depends on more than
imple IQ. Third, there are no known training programs that could guarantee this
esult.

Module 63 Studying Genetic and Environmental Influences on Intelligence

Page 651

A check on your understanding of heritability: If environments become more equal, the heritability of intelligence will

a. increase.

b. decrease.

c. be unchanged.

nswer: a. (Heritability—variation explained by genetic influences—will increase s environmental variation decreases.)

Module 64 Group Differences and the Question of Bias

Page 659

What psychological principle helps explain why women tend to perform more poorly when they believe their online chess opponent is male?

nswer: stereotype threat

What is the difference between a test that is biased culturally, and a test that is biased in terms of its validity?

nswer: A test may be *culturally* biased if higher scores are achieved by those with ertain cultural experiences. That same test may not be biased in terms of *validity* if predicts what it is supposed to predict. For example, the SAT may be culturally iased in favor of those with experience in the U.S. school system, but it does still ccurately predict U.S. college success.

Unit XII

Abnormal Behavior

Module 65 Introduction to Psychological Disorders

Page 672

A lawyer is distressed by feeling the need to wash his hands 100 times a day. He has little time to meet with clients, and his colleagues are wondering about his competence. His behavior would probably be labeled disordered, because it is ______________—that is, it interferes with his day-to-day life.

nswer: dysfunctional or maladaptive

Are psychological disorders universal or culture-specific? Explain with examples.

nswer: Some psychological disorders are culture-specific. For example, anorexia ervosa occurs mostly in Western cultures, and *taijin-kyofusho* appears largely in apan. Other disorders, such as schizophrenia, are universal—they occur in all ultures.

What is the value, and what are the dangers, of labeling individuals with disorders?

nswer: Therapists and others apply disorder labels to communicate with one nother using a common language, and to share concepts during research. Clients nay benefit from knowing that they are not the only ones with these symptoms. The angers of labeling people are that (1) people may begin to act as they have been ıbeled, and (2) the labels can trigger assumptions that will change people’s ehavior toward those labeled.

Page 675

What is the biopsychosocial approach, and why is it important in our understanding of psychological disorders?

nswer: Biological, psychological, and social-cultural influences combine to roduce psychological disorders. This approach helps us understand that our well-eing is affected by our genes, brain functioning, inner thoughts and feelings, and ıe influences of our social and cultural environments.

What is the relationship between poverty and psychological disorders?

nswer: Poverty-related stresses can help trigger disorders, but disabling disorders an also contribute to poverty. Thus, poverty and disorder are often a chicken-and-gg situation; it’s hard to know which came first.

Module 66 Anxiety Disorders, Obsessive-Compulsive Disorder, and Posttraumatic Stress Disorder

Page 679

Unfocused tension, apprehension, and arousal are symptoms of ______________ ______________ disorder.

nswer: generalized anxiety

Those who experience unpredictable periods of terror and intense dread, accompanied by frightening physical sensations, may be diagnosed with a _____________ disorder.

Answer: panic

If a person is focusing anxiety on specific feared objects or situations, that person may have a _____________.

Answer: phobia

Page 681

Those who express anxiety through unwanted repetitive thoughts or actions may have a(n) _____________-_____________ disorder.

Answer: obsessive-compulsive

Those with symptoms of recurring memories and nightmares, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia for weeks after a traumatic event may be diagnosed with _____________ _____________ disorder.

Answer: posttraumatic stress

Page 684

Researchers believe that conditioning and cognitive processes contribute to anxiety-related disorders. What *biological* factors also contribute to these disorders?

Answer: Biological factors include inherited temperament differences and other ene variations; experience-altered brain pathways; and inherited responses that had urvival value for our distant ancestors.

Module 67 Depressive Disorders, Bipolar Disorder, Suicide, and Self-Injury

Page 697

What does it mean to say that “depression is a whole-body disorder”?

Answer: Many factors contribute to depression, including the biological influences f genetics and brain function. Social-cognitive factors also matter, including the teraction of explanatory style, mood, our responses to stressful experiences, and hanges in our patterns of thinking and behaving. Depression involves the whole ody and may disrupt sleep, energy, and concentration.

Module 68 Schizophrenia

Page 704

A person with schizophrenia who has _____________ (positive/negative) symptoms may have an expressionless face and toneless voice. These symptoms are most common with _____________ (chronic/acute) schizophrenia and are not likely to respond to drug therapy. Those with _____________ (positive/negative) symptoms are likely to experience delusions, and, if the symptoms have arisen suddenly, to be diagnosed with _____________ (chronic/acute) schizophrenia, which is much more likely to respond to drug therapy.

nswer: negative; chronic; positive; acute

What factors contribute to the onset and development of schizophrenia?

nswer: Biological factors include abnormalities in brain structure and function and genetic predisposition to the disorder. Environmental factors such as nutritional eprivation, exposure to virus, and maternal stress contribute by activating the genes at increase risk. Exposure to many environmental triggers can increase the odds of eveloping schizophrenia.

Module 69 Other Disorders

Page 708

What does *somatic* mean, and how does it apply to *somatic symptom disorders*?

nswer: Somatic symptoms are bodily symptoms. A somatic disorder is one in hich symptoms take a somatic (bodily) form without apparent physical cause.

Page 710

The psychodynamic and learning perspectives agree that dissociative identity disorder symptoms are ways of dealing with anxiety. How do their

explanations differ?

nswer: The psychodynamic explanation of DID symptoms is that they are efenses against anxiety generated by unacceptable urges. The learning perspective ttempts to explain these symptoms as behaviors that have been reinforced by elieving anxiety.

Page 714

How do biological and psychological factors contribute to antisocial personality disorder?

nswer: Twin and adoption studies show that biological relatives of people with is disorder are at increased risk for antisocial behavior. Researchers have also bserved differences in the brain activity and structure of antisocial criminals. egative environmental factors, such as poverty or childhood abuse, may channel enetic traits such as fearlessness in more dangerous directions—toward aggression nd away from social responsibility.

People with ______________ ______________ (anorexia nervosa/bulimia nervosa) continue to want to lose weight even when they are underweight. Those with ______________ ______________ (anorexia nervosa/bulimia nervosa) tend to have weight that fluctuates within or above normal ranges.

nswer: anorexia nervosa; bulimia nervosa

Unit XIII

Treatment of Abnormal Behavior

Module 70 Introduction to Therapy, and Psychodynamic and Humanistic Therapies

Page 727

In psychoanalysis, when patients experience strong feelings for their therapist, this is called ______________. Patients are said to demonstrate anxiety when they put up mental blocks around sensitive memories, indicating ______________. The therapist will attempt to provide insight into the

underlying anxiety by offering a(n) _____________ of the mental blocks.

nswer: transference; resistance; interpretation

Module 71 Behavior, Cognitive, and Group Therapies

Page 733

What might a psychodynamic therapist say about Mowrer’s therapy for bed-wetting? How might a behavior therapist defend it?

nswer: A psychodynamic therapist might be more interested in helping the child evelop insight about the underlying problems that have caused the bed-wetting esponse. A behavior therapist would be more likely to agree with Mowrer that the ed-wetting symptom *is* the problem, and that counterconditioning the unwanted ehavior would indeed bring emotional relief.

Some maladaptive behaviors are learned. What hope does this fact provide?

nswer: If a behavior can be learned, it can be *un*learned, and replaced by other ore adaptive responses.

Exposure therapies and aversive conditioning are applications of _____________ conditioning. Token economies are an application of _____________ conditioning.

nswer: classical; operant

Page 739

How do the humanistic and cognitive therapies differ?

nswer: By reflecting clients’ feelings in a nondirective setting, the *humanistic erapies* attempt to foster personal growth by helping clients become more self-ware and self-accepting. By making clients aware of self-defeating patterns of inking, *cognitive therapies* guide people toward more adaptive ways of thinking bout themselves and their world.

A critical attribute of _____________ _____________, developed by Aaron Beck, focuses on the belief that changing people’s thinking can change their functioning.

nswer: cognitive therapy

What is cognitive-behavioral therapy, and what sorts of problems does this therapy best address?

nswer: This integrative therapy helps people change self-defeating thinking and ehavior. It has been shown to be effective for those with anxiety disorders, bsessive-compulsive disorder, depressive disorders, bipolar disorder, and eating isorders.

Module 72 Evaluating Psychotherapies

Page 745

How might the *placebo effect* bias clients' and clinicians' appraisals of the effectiveness of psychotherapies?

nswer: The *placebo effect* is the healing power of *belief* in a treatment. Patients nd therapists who expect a treatment to be effective may believe it was.

Therapy is most likely to be helpful for those with problems that _____________ (are/are not) well-defined.

nswer: are

What is *evidence-based practice?*

nswer: Using this approach, therapists make decisions about treatment based on search evidence, clinical expertise, and knowledge of the client.

Page 749

Those who undergo psychotherapy are _____________ (more/less) likely to show improvement than those who do not undergo psychotherapy.

nswer: more

What does the evidence suggest about the efficacy of EMDR and light therapy?

nswer: light therapy

Module 73 The Biomedical Therapies and Preventing Psychological Disorders

Page 752

What are some examples of lifestyle changes we can make to enhance our mental health?

nswer: Exercise regularly, get enough sleep, get more exposure to light (get utside or use a light box), nurture important relationships, redirect negative inking, and eat a diet rich in omega-3 fatty acids.

Page 759

How do researchers determine if particular drug therapies are effective?

nswer: Researchers assign people to treatment and no-treatment conditions to see those who receive the drug therapy improve more than those who don’t. Double-lind controlled studies are most effective. If neither the therapist nor the client nows which participants have received the drug treatment, then any difference etween the treated and untreated groups will reflect the drug treatment’s actual ffect.

The drugs given most often to treat depression are called _____________. Schizophrenia is often treated with _____________ drugs.

nswer: antidepressants; antipsychotic

Page 761

Severe depression that has not responded to other therapy may be treated with _____________ _____________, which can cause brain seizures and memory loss. More moderate neural stimulation techniques designed to help alleviate depression include _____________ direct current stimulation, _____________ _____________ magnetic stimulation, and _____________-_____________ stimulation.

nswer: electroconvulsive therapy (ECT); repetitive transcranial; deep-brain

What is the difference between preventive mental health and the psychological and biomedical therapies?

nswer: Psychological and biomedical therapies attempt to relieve people’s ffering from psychological disorders. Preventive mental health attempts to prevent ffering by identifying and eliminating the conditions that cause disorders.

Unit XIV

Social Psychology

Module 74 Attribution, Attitudes, and Actions

Page 773

Driving to school one snowy day, Marco narrowly misses a car that slides through a red light. “Slow down! What a terrible driver,” he thinks to himself. Moments later, Marco himself slips through an intersection and yelps, “Wow! These roads are awful. The city plows need to get out here.” What social psychology principle has Marco just demonstrated? Explain.

nswer: By attributing the other person’s behavior to the person (“he’s a terrible river”) and his own to the situation (“these roads are awful”), Marco has exhibited e *fundamental attribution error.*

How do our attitudes and our actions affect each other?

nswer: Our attitudes often influence our actions as we behave in ways consistent ith our beliefs. However, our actions also influence our attitudes; we come to elieve in what we have done.

When people act in a way that is not in keeping with their attitudes, and then change their attitudes to match those actions, _____________ _____________ theory attempts to explain why.

nswer: cognitive dissonance

Module 75 Conformity and Obedience

Page 782

Despite her mother’s pleas to use a more ergonomic backpack, Antonia insists on trying to carry all of her books to school in an oversized purse the way her

fashionable friends all seem to do. Antonia is affected by what type of social influence?

nswer: normative social influence

Psychology’s most famous obedience experiments, in which most participants obeyed an authority figure’s demands to inflict presumed painful, dangerous shocks on an innocent participant, were conducted by social psychologist ______________ ______________.

nswer: Stanley Milgram

What types of situations have researchers found to be most likely to encourage obedience in participants?

nswer: The Milgram studies showed that people were most likely to follow orders hen the experimenter was nearby and was a legitimate authority figure, the victim as not nearby, and there were no models for defiance.

Module 76 Group Behavior

Page 786

What is social facilitation, and why is it more likely to occur with a well-learned task?

nswer: This improved performance in the presence of others is most likely to ccur with a well-learned task, because the added arousal caused by an audience nds to strengthen the most likely response. This also predicts poorer performance n a difficult task in others’ presence.

People tend to exert less effort when working with a group than they would alone, which is called ______________ ______________.

nswer: social loafing

You are organizing a meeting of fiercely competitive political candidates. To add to the fun, friends have suggested handing out masks of the candidates’ faces for supporters to wear. What phenomenon might these masks engage?

nswer: The anonymity provided by the masks, combined with the arousal of the ontentious setting, might create deindividuation (lessened self-awareness and self-straint).

Page 790

When like-minded groups discuss a topic, and the result is the strengthening of the prevailing opinion, this is called ______________ ______________.

nswer: group polarization

When a group's desire for harmony overrides its realistic analysis of other options, ______________ has occurred.

nswer: groupthink

Module 77 Prejudice and Discrimination

Page 799

What is the difference between prejudice and discrimination?

nswer: Prejudice is an unjustifiable and usually negative *attitude* toward a group nd its members, while unjustifiable negative *behavior* is discrimination.

When prejudiced judgment causes us to blame an undeserving person for a problem, that person is called a ______________.

nswer: scapegoat

Module 78 Aggression

Page 806

What psychological, biological, and social-cultural influences interact to produce aggressive behaviors?

nswer: Our biology (our genes, neural systems, and biochemistry—including stosterone and alcohol levels) influences our aggressive tendencies. Psychological ctors (such as frustration, previous rewards for aggressive acts, and observation of thers' aggression) can trigger any aggressive tendencies we may have. Social fluences, such as exposure to violent media or being ostracized from a group, and ultural influences, such as whether we've grown up in a "culture of honor" or a ther-absent home, can also affect our aggressive responses.

Module 79 Attraction

Page 812

People tend to marry someone who lives or works nearby. This is an example of the _____________ _____________ _____________ in action.

nswer: mere exposure effect

How does being physically attractive influence others’ perceptions?

nswer: Being physically attractive tends to elicit positive first impressions. People nd to assume that attractive people are healthier, happier, and more socially skilled an others are.

Page 814

How does the two-factor theory of emotion help explain *passionate love?*

nswer: Emotions consist of (1) physical arousal and (2) our interpretation of that rousal. Researchers have found that any source of arousal (running, fear, laughter) ay be interpreted as passion in the presence of a desirable person.

Two vital components for maintaining companionate love are _____________ and _____________-_____________.

nswer: equity; self-disclosure

Module 80 Altruism, Conflict, and Peacemaking

Page 818

Why didn’t anybody help Kitty Genovese? What social psychology principle did this incident illustrate?

nswer: In the presence of others, an individual is less likely to notice a situation, orrectly interpret it as an emergency, and take responsibility for offering help. The itty Genovese case demonstrated this *bystander effect*, as each witness assumed any others were also aware of the event.

Page 823

Why do sports fans tend to feel a sense of satisfaction when their archrival team loses? Why do such feelings, in other settings, make conflict resolution

more challenging?

nswer: Sports fans may feel they are part of an *ingroup* that sets itself apart from n *outgroup* (fans of the archrival team). Ingroup bias tends to develop, leading to rejudice and the view that the outgroup “deserves” misfortune. So, the archrival am’s loss may seem justified. In conflicts, this kind of thinking is problematic, specially when each side in the conflict develops *mirror-image perceptions* of the ther (distorted, negative images that are ironically similar).

What are some ways to reconcile conflicts and promote peace?

nswer: Peacemakers should encourage equal-status contact, cooperation to chieve *superordinate goals* (shared goals that override differences), understanding rough communication, and reciprocated conciliatory gestures (each side gives a ttle).

Enrichment Modules

Module 81 Influences on Drug Use

Page 832

Why do tobacco companies try so hard to get customers hooked as teens?

nswer: Nicotine is powerfully addictive, and those who start paving the neural athways when young may find it very hard to stop using it. As a result, tobacco ompanies may have lifelong customers. Moreover, evidence suggests that if igarette manufacturers haven’t hooked customers by early adulthood, they most kely won’t.

Studies have found that people who begin drinking in their early teens are much more likely to develop alcohol use disorder than those who begin at age 21 or after. What possible explanations might there be for this correlation?

nswer: Possible explanations include (a) biological factors (a person could have a iological predisposition to both early use and later abuse, or alcohol use could odify a person’s neural pathways); (b) psychological factors (early use could stablish taste preferences for alcohol); and (c) social-cultural factors (early use ould influence enduring habits, attitudes, activities, or peer relationships that could ster alcohol use disorder).

Module 82 Psychology at Work

Page 839

What is the value of finding flow in our work?

nswer: We become more likely to view our work as fulfilling and socially useful, nd we experience higher self-esteem, competence, and overall well-being.

A human resources director explains to you that “I don’t bother with tests or references. It’s all about the interview.” Based on I/O psychology research, what concerns does this raise?

nswer: (1) Interviewers may presume people are what they seem to be in terviews. (2) Interviewers’ preconceptions and moods color how they perceive terviewees’ responses. (3) Interviewers judge people relative to other recent terviewees. (4) Interviewers tend to track the successful careers of those they hire, ot the successful careers of those they reject. (5) Interviews tend to disclose rospective workers’ good intentions, not their habitual behaviors.

Page 844

What are the two basic types of leadership, and how do the most effective managers employ these leadership strategies?

nswer: Task leadership is goal-oriented. Managers using this style set standards, rganize work, and focus attention on goals. Social leadership is group-oriented. anagers using this style build teamwork, mediate conflict, and offer support. esearch indicates that effective managers exhibit both task and social leadership, epending on the situation and the person.

What characteristics are important for transformational leaders?

nswer: Transformational leaders are able to inspire others to share a vision and ommit themselves to a group’s mission. They tend to be naturally extraverted and t high standards.

Page 846

What is the *curse of knowledge,* and what does it have to do with the work of human factors psychologists?

nswer: To develop safer machines and work environments, human factors
sychologists stay mindful of the curse of knowledge—the tendency for experts to
istakenly assume that others share their knowledge.

Module 83 Animal Thinking and Language

Page 850

If your dog barks at a stranger at the door, does this qualify as language? What if the dog yips in a telltale way to let you know she needs to go out?

nswer: These are definitely communications. But if language consists of words
nd the grammatical rules we use to combine them to communicate meaning, few
cientists would label a dog’s barking and yipping as language.

Glossary

English	Español
A	
absolute threshold the minimum stimulus energy needed to detect a particular stimulus 50 percent of the time. (p. 163)	**umbral absoluto** el mínimo de energía que requiere un estímulo para tener 50 por ciento de probabilidades de ser detectado. (p. 163)
accommodation (1) in sensation and perception, the process by which the eye's lens changes shape to focus near or far objects on the retina. (2) in developmental psychology, adapting our current understandings (schemas) to incorporate new information. (pp. 177, 498)	**acomodación** (1) en sensación y percepción, proceso por el cual la lente del ojo cambia de forma para enfocar objetos cercanos o lejanos en la retina. (2) en psicología del desarrollo, adaptar nuestros entendimientos actuales (esquemas) para incorporar información nueva. (pp. 177, 498)
achievement motivation a desire for significant accomplishment, for mastery of skills or ideas, for control, and for attaining a high standard. (p. 428)	**motivación del logro** deseo de conseguir un logro significante, de dominar habilidades o ideas, de control, y de alcanzar un estándar elevado. (p. 428)
achievement test a test designed to assess what a person has learned. (p. 632)	**prueba de rendimiento** prueba diseñada para evaluar los aprendizajes de una persona. (p. 632)
acquisition in classical conditioning, the initial stage, when one links a neutral stimulus and an unconditioned stimulus so that the neutral stimulus begins triggering the conditioned response. In operant conditioning, the strengthening of a reinforced response. (p. 275)	**adquisición** etapa inicial, en el condicionamiento clásico, donde uno relaciona un estímulo neutral con un estímulo no condicionado de tal manera que el estímulo neutral provoca una respuesta condicionada. En el condicionamiento operante, es el fortalecimiento de una respuesta reforzada.

	(p. 275)
action potential a neural impulse; a brief electrical charge that travels down an axon. (p. 83)	**acción potencial** un impulso neural; una breve carga eléctrica que viaja por un axón. (p. 83)
active listening empathic listening in which the listener echoes, restates, and clarifies. A feature of Rogers’ client-centered therapy. (p. 726)	**escucha activa** forma de escuchar con empatía en la cual, la persona que escucha resuena, reafirma y clarifica las palabras de la otra persona. Es un rasgo de la terapia centrada en el cliente de Carl Rogers. (p. 726)
acute schizophrenia (also called *reactive schizophrenia*) a form of schizophrenia that can begin at any age; frequently occurs in response to a traumatic event. (p. 701)	**esquizofrenia aguda** (también conocida como *esquizofrenia reactiva*) tipo de esquizofrenia que puede comenzar a cualquier edad; con frecuencia ocurre como respuesta a un evento traumático. (p. 701)
adaptation-level phenomenon our tendency to form judgments (of sounds, of lights, of income) relative to a neutral level defined by our prior experience. (p. 476)	**fenómeno del nivel de adaptación** nuestra tendencia a formar juicios (de sonidos, de luces, de ingresos) en relación con un nivel neutral definido por nuestra experiencia previa. (p. 476)
adolescence the transition period from childhood to adulthood, extending from puberty to independence. (p. 533)	**adolescencia** el periodo de transición de la infancia hacia la edad adulta, que se extiende desde la pubertad hasta la independencia. (p. 533)
adrenal [ah-DREEN-el] **glands** a pair of endocrine glands that sit just above the kidneys and secrete hormones (epinephrine and norepinephrine) that help arouse the body in times of stress. (p. 95)	**glándulas suprarrenales** par de glándulas endócrinas, ubicadas en la parte superior de los riñones, que secretan hormonas (epinefrina, también conocida como adrenalina, y norepinefrina, también conocida como noradrenalina) que ayudan a despertar el cuerpo en tiempos de estrés . (p. 95)
aerobic exercise sustained exercise that increases heart and lung fitness; also helps alleviate depression and anxiety. (p. 467)	**ejercicio aeróbico** ejercicio continuo que mejora la condición pulmonar y cardiovascular; también ayuda a aliviar la depresión y ansiedad. (p. 467)
affiliation need the need to build relationships and to feel	**necesidad de afiliación** la necesidad de construir relaciones y

part of a group. (p. 423)	sentirse parte de un grupo. (p. 423)
aggression any physical or verbal behavior intended to harm someone physically or emotionally. (pp. 521, 801)	**agresión** cualquier comportamiento físico o verbal que tiene la intención de lastimar, ya sea emocionalmente o físicamente, a otra persona. (pp. 521, 801)
agonist a molecule that increases a neurotransmitter's action. (p. 88)	**agonista** molécula que incrementa la acción de un neurotransmisor. (p. 88)
agoraphobia fear or avoidance of situations, such as crowds or wide open places, where one has felt loss of control and panic. (p. 678)	**agorafobia** miedo o tendencia a evitar situaciones, como multitudes o espacios abiertos, donde uno siente pérdida de control y pánico. (p. 678)
AIDS (acquired immune deficiency syndrome) a life-threatening, sexually transmitted infection caused by the *human immunodeficiency virus (HIV)*. AIDS depletes the immune system, leaving the person vulnerable to infections. (p. 547)	**SIDA** (síndrome de inmunodeficiencia adquirida) infección mortal de transmisión sexual provocada por el *virus de inmunodeficiencia humana VIH*). El SIDA afecta al sistema inmune y deja a la persona vulnerable a infecciones. (p. 547)
alcohol use disorder (popularly known as *alcoholism*) alcohol use marked by tolerance, withdrawal, and a drive to continue problematic use. (p. 255)	**trastorno de abuso de alcohol** (conocido popularmente como *alcoholismo*) consumo de alcohol marcado por la tolerancia, retraimiento y el impulso de continuar con el uso problemático. (p. 255)
algorithm a methodical, logical rule or procedure that guarantees solving a particular problem. Contrasts with the usually speedier—but also more error-prone—use of *heuristics*. (p. 370)	**algoritmo** regla o procedimiento metódico y lógico que garantiza la resolución de un problema particular. Contrasta con el uso de la heurística que es más veloz pero también más propensa a los errores. (p. 370)
all-or-none response a neuron's reaction of either firing (with a full-strength response) or not firing. (p. 83)	**respuesta de todo o nada** la reacción de una neurona que dispara (con una respuesta total) o no dispara. (p. 83)
alpha waves the relatively slow brain waves of a relaxed, awake state. (p. 232)	**ondas alfa** las ondas cerebrales relativamente lentas del estado despierto y relajado. (p. 232)
altruism	**altruismo**

unselfish regard for the welfare of others. (p. 816)	consideración generosa por el bienestar de otros (p. 816)
Alzheimer’s disease a neurocognitive disorder marked by neural plaques, often with onset after age 80, and entailing a progressive decline in memory and other cognitive abilities. (p. 563)	**enfermedad de Alzheimer** trastorno neurocognitivo marcado por la aparición de placas seniles, que generalmente inicia después de los 80 años y conlleva un declive progresivo en la memoria y otras habilidades cognitivas. (p. 563)
amphetamines drugs, such as methamphetamine, that stimulate neural activity, causing accelerated body functions and associated energy and mood changes. (p. 260)	**anfetaminas** sustancias, como la metanfetamina, que estimula la actividad neural y provoca una aceleración en las funciones corporales y que está asociada con cambios en los niveles de energía y en el estado del humor. (p. 260)
amygdala [uh-MIG-duh-la] two lima-bean-sized neural clusters in the limbic system; linked to emotion. (p. 104)	**amígdalas** dos cúmulos neurales del tamaño de una haba que forman parte del sistema límbico; están vinculadas a las emociones. (p. 104)
androgyny displaying both traditional masculine and feminine psychological characteristics. (p. 526)	**androginia** cuando una persona muestra rasgos psicológicos tradicionales tanto masculinos como femeninos. (p. 526)
anorexia nervosa an eating disorder in which a person (usually an adolescent female) maintains a starvation diet despite being significantly underweight; sometimes accompanied by excessive exercise. (p. 712)	**anorexia nerviosa** trastorno alimenticio en el cual una persona (normalmente mujer adolescente) mantiene una dieta de hambre a pesar de tener el peso significativamente por debajo de lo normal; a veces también conlleva ejercicio en exceso. (p. 712)
antagonist a molecule that inhibits or blocks a neurotransmitter’s action. (p. 89)	**antagonista** molécula que inhibe la acción de un neurotransmisor. (p. 89)
anterograde amnesia an inability to form new memories. (p. 351)	**amnesia anterógrada** la incapacidad de formar nuevas memorias. (p. 351)
antianxiety drugs drugs used to control anxiety and agitation. (p. 754)	**ansiolíticos** medicamentos para controlar la ansiedad y la agitación. (p. 754)

antidepressant drugs drugs used to treat depression, anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder. (Several widely used antidepressant drugs are *selective serotonin reuptake inhibitors—SSRIs*.) (p. 754)	**antidepresivos** medicamentos para tratar depresión, trastornos de ansiedad, trastornos obsesivo-compulsivos y el trastorno por estrés postraumático. (Varios de los antidepresivos comunes son inhibidores selectivos de la recaptación de serotonina—ISRS.) (p. 754)
antipsychotic drugs drugs used to treat schizophrenia and other forms of severe thought disorder. (p. 753)	**medicamentos antipsicóticos** medicamentos que se usan para tratar la esquizofrenia y otros tipos de trastorno severo del pensamiento. (p. 753)
antisocial personality disorder a personality disorder in which a person (usually a man) exhibits a lack of conscience for wrongdoing, even toward friends and family members; may be aggressive and ruthless or a clever con artist. (p. 710)	**trastorno de la personalidad antisocial** trastorno de la personalidad en el cual una persona (normalmente hombre) no está consciente de haber causado un mal, incluso hacia amigos o familiares puede ser agresivo, despiadado o incluso puede llegar a ser un astuto estafador. (p. 710)
anxiety disorders psychological disorders characterized by distressing, persistent anxiety or maladaptive behaviors that reduce anxiety. (p. 677)	**trastornos de ansiedad** trastornos psicológicos caracterizados por estados de angustia, ansiedad persistente o que muestran una conducta inadaptada que reduce la ansiedad. (p. 677)
aphasia impairment of language, usually caused by left hemisphere damage either to Broca's area (impairing speaking) or to Wernicke's area (impairing understanding). (p. 387)	**afasia** discapacidad del lenguaje, generalmente provocado por daños en el hemisferio izquierdo del cerebro, ya sea en el área de Broca (que afecta al habla) o al área de Wernicke (que afecta la comprensión). (p. 387)
applied research scientific study that aims to solve practical problems. (p. 24)	**investigación aplicada** estudios científicos que buscan resolver problemas prácticos. (p. 24)
aptitude test a test designed to predict a person's future performance; *aptitude* is the capacity to learn. (p. 632)	**prueba de aptitud** prueba diseñada para predecir el desempeño futuro de una persona; aptitud capacidad para aprender. (p. 632)
asexual having no sexual attraction to others. (p. 418)	**asexual** que no siente atracción sexual hacia otros. (p. 418)

assimilation interpreting our new experiences in terms of our existing schemas. (p. 498)	**asimilación** interpretar nuestras nuevas experiencias según nuestros esquemas existentes (p. 498)
association areas areas of the cerebral cortex that are not involved in primary motor or sensory functions; rather, they are involved in higher mental functions such as learning, remembering, thinking, and speaking. (p. 114)	**áreas de asociación** áreas de la corteza cerebral que no se involucran en las funciones primarias motrices o sensoriales; en vez de eso, se involucran en funciones mentales superiores como el aprender, recordar, pensar y hablar. (p. 114)
associative learning learning that certain events occur together. The events may be two stimuli (as in classical conditioning) or a response and its consequence (as in operant conditioning). (p. 271)	**aprendizaje asociativo** aprender que ciertos sucesos ocurren juntos. Los sucesos pueden ser dos estímulos (como en el condicionamiento clásico) o una respuesta y su consecuencia (como en el condicionamiento operativo). (p. 271)
attachment an emotional tie with another person; shown in young children by their seeking closeness to their caregiver and showing distress on separation. (p. 509)	**apego** conexión emocional con otra persona; la muestran los niños pequeños al buscar cercanía con sus cuidadores y aflicción al separse de ellos. (p. 509)
attention-deficit/hyperactivity disorder (ADHD) a psychological disorder marked by extreme inattention and/or hyperactivity and impulsivity. (p. 670)	**trastorno por déficit de atención con hiperactividad (TDAH)** trastorno psicológico marcado por una falta de atención extrema y/o hiperactividad e impulsividad. (p. 670)
attitude feelings, often influenced by our beliefs, that predispose us to respond in a particular way to objects, people, and events. (p. 770)	**actitud** sentimientos, muchas veces influenciados por nuestras creencias, que nos predisponen a responder de una manera especial a los objetos, la gente y los sucesos. (p. 770)
attribution theory the theory that we explain someone's behavior by crediting either the situation or the person's disposition. (p. 768)	**teoría de atribución** teoría según la cual el comportamiento de alguien se atribuye a una situación o a la disposición de aquella persona. (p. 768)
audition the sense or act of hearing. (p. 198)	**audición** sentido o acto de oír. (p. 198)
autism spectrum disorder (ASD) a disorder that appears in childhood and is	**trastorno del espectro autista (ASD, en inglés)**

marked by significant deficiencies in communication and social interaction, and by rigidly fixated interests and repetitive behaviors. (p. 505)	trastorno que aparece en la infancia, marcado por deficiencias significativas de comunicación e interacción social, y por una fijación rígida en sus intereses y comportamientos repetitivos. (p. 505)
automatic processing unconscious encoding of incidental information, such as space, time, and frequency, and of well-learned information, such as word meanings. (p. 331)	**procesamiento automático** codificación inconsciente de información incidental, como espacio, tiempo y frecuencia, y de información bien aprendida, como los significados de palabras. (p. 331)
autonomic [aw-tuh-NAHM-ik] **nervous system (ANS)** the part of the peripheral nervous system that controls the glands and the muscles of the internal organs (such as the heart). Its sympathetic division arouses; its parasympathetic division calms. (p. 93)	**sistema nervioso autónomo (ANS, en inglés)** la parte del sistema nervioso periférico que controla los músculos y las glándulas de los órganos internos (por ejemplo, el corazón). Su división simpática estimula; su división parasimpática tranquiliza. (p. 93)
availability heuristic estimating the likelihood of events based on their availability in memory; if instances come readily to mind (perhaps because of their vividness), we presume such events are common. (p. 373)	**heurística de la disponibilidad** estimar la probabilidad de un evento a partir de la disponibilidad de eventos similares en la memoria; si hay instancias que vienen rápidamente a la mente (quizás por su intensidad), suponemos que tales eventos son comunes. (p. 373)
aversive conditioning a type of counterconditioning that associates an unpleasant state (such as nausea) with an unwanted behavior (such as drinking alcohol). (p. 731)	**condicionamiento aversivo** tipo de contra-condicionamiento que asocia estados desagradables (como la náusea) con un comportamiento no deseado (como beber alcohol). (p. 731)
axon the neuron extension that passes messages through its branches to other neurons or to muscles or glands. (p. 82)	**axón** extensión de las neuronas que transmite mensajes a través de sus terminales a otras neuronas o a músculos o glándulas. (p. 82)
B	
babbling stage beginning around 4 months, the stage of speech development in which an infant spontaneously utters various sounds at first unrelated to the household language. (p. 384)	**etapa de balbuceo** etapa de desarrollo del habla, que comienza alrededor de la edad de cuatro meses, en la que un infante repentinamente emite sonidos diversos que al principio no tienen relación con el lenguaje del hogar. (p. 384)

barbiturates drugs that depress central nervous system activity, reducing anxiety but impairing memory and judgment. (p. 257)	**barbitúricos** medicamentos que deprimen la actividad del sistema nervioso central, de tal manera que reducen la ansiedad pero afectan la memoria y el juicio. (p. 257)
basal metabolic rate the body's resting rate of energy output. (p. 411)	**tasa metabólica basal** tasa de producción de energía del cuerpo en reposo. (p. 411)
basic research pure science that aims to increase the scientific knowledge base. (p. 24)	**investigación básica** ciencia pura que busca incrementar la base de conocimiento científico. (p. 24)
basic trust according to Erik Erikson, a sense that the world is predictable and trustworthy; said to be formed during infancy by appropriate experiences with responsive caregivers. (p. 513)	**confianza básica** de acuerdo con Erik Erikson, la sensación según la cual el mundo es un lugar predecible y digno de confianza; se dice que se forma durante la infancia por medio de experiencias apropiadas con cuidadores responsivos. (p. 513)
behavior feedback effect the tendency of behavior to influence our own and others' thoughts, feelings, and actions. (p. 448)	**efecto de retroalimentación del comportamiento** tendencia del comportamiento de influir en los pensamientos, sentimientos y acciones propias y ajenas. (p. 448)
behavior genetics the study of the relative power and limits of genetic and environmental influences on behavior. (pp. 14, 129)	**genética conductual** el estudio del poder relativo y las limitaciones de las influencias genéticas y ambientales sobre el comportamiento. (pp. 14, 129)
behavior therapy therapy that applies learning principles to the elimination of unwanted behaviors. (p. 729)	**terapia del comportamiento** terapia que aplica principios de aprendizaje a la eliminación de comportamientos no deseados. (p. (p. 729)
behavioral approach focuses on the effects of learning on our personality development. (p. 606)	**enfoque conductual** se enfoca en los efectos del aprendizaje en el desarrollo de nuestra personalidad. (p. 606)
behavioral psychology the scientific study of observable behavior, and its explanation by principles of learning. (p. 17)	**psicología del comportamiento** estudio científico del comportamiento observable, y su explicación según principios de aprendizaje. (p. 17)

behaviorism the view that psychology (1) should be an objective science that (2) studies behavior without reference to mental processes. Most psychologists today agree with (1) but not with (2). (pp. 10, 272)	**conductismo** perspectiva según la cual la psicología (1) debe ser una ciencia objetiva que (2) estudia el comportamiento sin referencia a los procesos mentales. La mayoría de los psicólogos están de acuerdo con (1) pero no con (2). (pp. 10, 272)
belief perseverance clinging to one's initial conceptions after the basis on which they were formed has been discredited. (p. 376)	**perseverancia de las creencias** aferrarse a nuestras concepciones iniciales aún cuando las bases que las sostienen han sido desacreditadas. (p. 376)
binge-eating disorder significant binge-eating episodes, followed by distress, disgust, or guilt, but without the compensatory behavior that marks bulimia nervosa. (p. 713)	**trastorno por atracón** episodios de ingestión compulsiva de alimentos, seguidos por angustia, asco o sentimientos de culpa, pero sin el comportamiento de compensación típico de la bulimia nervosa. (p. 713)
binocular cue a depth cue, such as retinal disparity, that depends on the use of two eyes. (p. 189)	**pista binocular** pista de profundidad, como la disparidad retiniana, que depende del uso de ambos ojos. (p. 189)
biofeedback a system for electronically recording, amplifying, and feeding back information regarding a subtle physiological state, such as blood pressure or muscle tension. (p. 296)	**biorretroalimentación** sistema electrónico de grabación, amplificación y retroalimentación de información de un estado psicológico sutil, como la presión arterial o la tensión muscular. (p. 296)
biological psychology the scientific study of the links between biological (genetic, neural, hormonal) and psychological processes. (Some biological psychologists call themselves *behavioral neuroscientists, neuropsychologists, behavior geneticists, physiological psychologists,* or *biopsychologists*.) (p. 17)	**psicología biológica** el estudio científico de la relación entre los procesos biológicos (genéticos, neurales, hormonales) y psicológicos. (Algunos psicólogos biológicos se hacen llamar neurocientíficos del comportamiento, neuropsicólogos, genetistas conductuales, psicólogos de la fisiología, o biopsicólogos). (p. 17)
biomedical therapy prescribed medications or procedures that act directly on the person's physiology. (p. 722)	**terapia biomédica** medicamentos recetados o procedimientos que actúan directamente sobre la psicología de una persona. (p. 722)
biopsychosocial approach	**enfoque biopsicológico**

an integrated approach that incorporates biological, psychological, and social-cultural viewpoints. (p. 17)	enfoque integrado que incorpora perspectivas biológicas, psicológicas y socioculturales. (p. 17)
bipolar disorder a disorder in which a person alternates between the hopelessness and lethargy of depression and the overexcited state of mania. (Formerly called *manic-depressive disorder*.) (p. 687)	**trastorno bipolar** trastorno en el cual una persona alterna entre el letargo y la desesperación de la depresión y la sobreexcitación del estado maníaco. (Anteriormente se conocía como trastorno maníaco-depresivo). (p. 687)
blind spot the point at which the optic nerve leaves the eye, creating a "blind" spot because no receptor cells are located there. (p. 179)	**punto ciego** el punto donde el nervio óptico sale del ojo, y crea así un punto "ciego" por la ausencia de células receptoras en este sitio. (p. 179)
blindsight a condition in which a person can respond to a visual stimulus without consciously experiencing it. (p. 125)	**visión ciega** condición en la cual una persona puede responder a un estímulo visual sin experimentarlo de manera consciente. (p. 125)
bottom-up processing analysis that begins with the sensory receptors and works up to the brain's integration of sensory information. (p. 158)	**procesamiento abajo-arriba** análisis que comienza en los receptores sensoriales y avanza hacia la integración de información sensorial en el cerebro. (p. 158)
brainstem the oldest part and central core of the brain, beginning where the spinal cord swells as it enters the skull; the brainstem is responsible for automatic survival functions. (p. 102)	**tronco cerebral** la parte más vieja del cerebro y el núcleo central del cerebro, que comienza donde la médula se ensancha y entra en el cráneo; el tronco cerebral es responsable de las funciones automáticas de supervivencia . (p. 102)
Broca's area helps control language expression—an area of the frontal lobe, usually in the left hemisphere, that directs the muscle movements involved in speech. (p. 388)	**área de Broca** ayuda a controlar la expresión del lenguaje: región del lóbulo frontal, normalmente en el hemisferio izquierdo, que dirige los movimientos musculares involucrados en el habla. (p. 388)
bulimia nervosa an eating disorder in which a person's binge eating (usually of high-calorie foods) is followed by inappropriate weight-loss promoting behavior, such as vomiting, laxative use, fasting, or excessive exercise.	**bulimia nerviosa** trastorno alimenticio en el cual una persona ingiere compulsivamente alimentos (generalmente altos en calorías) seguido por un comportamiento inadecuado que promueve la pérdida de peso, como el

(p. 713)	vómito, el uso de laxantes, el ayuno o el ejercicio excesivo. (p. 713)
bystander effect the tendency for any given bystander to be less likely to give aid if other bystanders are present. (p. 817)	**efecto del espectador** tendencia que tienen las personas a no brindar ayuda si hay otras personas presentes. (p. 817)
C	
Cannon-Bard theory the theory that an emotion-arousing stimulus simultaneously triggers (1) physiological responses and (2) the subjective experience of emotion. (p. 433)	**teoría de Cannon-Bard** teoría de según la cual un estímulo que despierta emociones puede provocar simultáneamente (1) respuestas fisiológicas y (2) la experiencia subjetiva de la emoción. (p. 433)
case study a descriptive technique in which one individual or group is studied in depth in the hope of revealing universal principles. (p. 44)	**estudio de caso** técnica de observación en la cual se estudia a un individuo o grupo a profundidad con la esperanza de revelar principios universales. (p. 44)
catharsis in psychology, the idea that “releasing” aggressive energy (through action or fantasy) relieves aggressive urges. (p. 460)	**catarsis** en la psicología, la idea según la cual “liberar” energía agresiva (por medio de la acción o fantasía) ayuda a reducir impulsos agresivos en las personas. (p. 460)
cell body the part of a neuron that contains the nucleus; the cell’s life-support center. (p. 82)	**cuerpo celular** la parte de una neurona que contiene el núcleo; soporte vital de la célula. (p. 82)
central nervous system (CNS) the brain and spinal cord. (p. 92)	**sistema nervioso central (CNS, en inglés)** el cerebro y la espina dorsal. (p. 92)
central route persuasion occurs when interested people focus on the arguments and respond with favorable thoughts. (p. 771)	**ruta central de persuasión central** se produce cuando las personas interesadas se centran en los argumentos y responden con pensamientos favorables. (p. 771)
cerebellum [sehr-uh-BELL-um] the “little brain” at the rear of the brainstem; functions include processing sensory input, coordinating movement output and balance, and enabling nonverbal learning and memory. (p. 103)	**cerebelo** el “pequeño cerebro” ubicado en la parte posterior del tronco encefálico; sus funciones incluyen el procesamiento de información sensorial, la coordinación de los movimientos y el equilibrio y la habilitación del lenguaje no verbal y la memoria. (p. 103)

cerebral [seh-REE-bruhl] **cortex** the intricate fabric of interconnected neural cells covering the cerebral hemispheres; the body's ultimate control and information-processing center. (p. 109)	**corteza cerebral** capa delgada de neuronas conectadas entre sí, que forman los hemisferios cerebrales; es el principal centro de control y procesamiento de información del organismo. (p. 109)
change blindness failing to notice changes in the environment; a form of *inattentional blindness*. (p. 161)	**ceguera al cambio** no darse cuenta de cambios en el entorno. Una forma de ceguera por falta de atención. (p. 161)
chromosomes threadlike structures made of DNA molecules that contain the genes. (p. 130)	**cromosomas** estructuras semejantes a hilos conformadas de moléculas de ADN que contienen los genes. (p. 130)
chronic schizophrenia (also called *process schizophrenia*) a form of schizophrenia in which symptoms usually appear by late adolescence or early adulthood. As people age, psychotic episodes last longer and recovery periods shorten. (p. 700)	**esquizofrenia crónica** (también se le dice *esquizofrenia procesal*) tipo de esquizofrenia en la que los síntomas aparecen generalmente en la adolescencia tardía o adultez temprana. A medida que las personas envejecen, los episodios psicóticos se vuelven más largos y los períodos de recuperación se vuelven más cortos. (p. 700)
chunking organizing items into familiar, manageable units; often occurs automatically. (p. 333)	**agrupamiento** organizar artículos en unidades conocidas y manejables; a menudo ocurre automáticamente. (p. 333)
circadian [ser-KAY-dee-an] **rhythm** our biological clock; regular bodily rhythms (for example, of temperature and wakefulness) that occur on a 24-hour cycle. (p. 231)	**ritmo circadiano** reloj biológico; ritmos periódicos del organismo (por ejemplo, el de temperatura y estado de vigilia) que ocurren en ciclos de 24 horas. (p. 231)
classical conditioning a type of learning in which we link two or more stimuli; as a result, to illustrate with Pavlov's classic experiment, the first stimulus (a tone) comes to elicit behavior (drooling) in anticipation of the second stimulus (food). (p. 272)	**condicionamiento clásico** tipo de aprendizaje en el cual aprendemos a relacionar dos o más estímulos; como resultado, con el experimento clásico de Pavlov como ejemplo, el primer estímulo (un timbre) provoca un comportamiento (salivación) en anticipación del segundo estímulo (comida). (p. 272)
client-centered therapy	**terapia centrada en el cliente**

a humanistic therapy, developed by Carl Rogers, in which the therapist uses techniques such as *active listening* within an accepting, genuine, empathic environment to facilitate clients’ growth. (Also called *person-centered therapy*.) (p. 725)	terapia humanística, desarrollada por Carl Rogers, en la cual el o la terapeuta emplea técnicas como *escuchar activamente* dentro de un entorno de genuino de aceptación y empatía para facilitar el crecimiento de sus clientes. (Conocida también como *terapia centrada en la persona*). (p. 725)
clinical psychology a branch of psychology that studies, assesses, and treats people with psychological disorders. (p. 25)	**psicología clínica** rama de la psicología que estudia, evalúa y trata a personas con trastornos psicológicos. (p. 25)
cocaine a powerful and addictive stimulant derived from the coca plant; produces temporarily increased alertness and euphoria. (p. 259)	**cocaína** estimulante potente y adictivo derivado de la planta de coca; aumenta temporalmente el estado de alerta y produce sensaciones de euforia. (p. 259)
cochlea [KOHK-lee-uh] a coiled, bony, fluid-filled tube in the inner ear; sound waves traveling through the cochlear fluid trigger nerve impulses. (p. 199)	**cóclea** estructura tubular en forma de espiral, ósea y rellena de líquido que se halla en el oído interno; las ondas sonoras que pasan por el líquido coclear desencadenan impulsos nerviosos. (p. 199)
cochlear implant a device for converting sounds into electrical signals and stimulating the auditory nerve through electrodes threaded into the cochlea. (p. 201)	**implante coclear** dispositivo que convierte sonidos en señales eléctricas que estimulan el nervio auditivo mediante electrodos enhebrados en la cóclea. (p. 201)
cognition all the mental activities associated with thinking, knowing, remembering, and communicating. (pp. 365, 498)	**cognición** todas las actividades mentales asociadas con pensar, saber, recordar y comunicar. (pp. 365, 498)
cognitive dissonance theory the theory that we act to reduce the discomfort (dissonance) we feel when two of our thoughts (cognitions) are inconsistent. For example, when we become aware that our attitudes and our actions clash, we can reduce the resulting dissonance by changing our attitudes. (p. 773)	**teoría de la disonancia cognitiva** teoría según la cual actuamos para reducir la incomodidad (disonancia) cuando sentimos que dos de nuestros pensamientos (cogniciones) son disonantes. Por ejemplo, cuando nos damos cuenta que hay un choque entre nuestras actitudes y nuestras acciones, podemos reducir la disonancia resultante con cambios de actitud. (p. 773)
cognitive learning the acquisition of mental information,	**aprendizaje cognitivo** adquisición de información mental, ya sea a

whether by observing events, by watching others, or through language. (p. 272)	partir de la observación de acontecimientos, la observación de otras personas o a través del lenguaje. (p. 272)
cognitive map a mental representation of the layout of one's environment. For example, after exploring a maze, rats act as if they have learned a cognitive map of it. (p. 304)	**mapa cognitivo** imagen mental del trazado de nuestro entorno. Por ejemplo, después de recorrer un laberinto, las ratas actúan como si se hubieran aprendido un mapa del laberinto. (p. 304)
cognitive neuroscience the interdisciplinary study of the brain activity linked with cognition (including perception, thinking, memory, and language). (pp. 13, 124)	**neurociencia cognitiva** estudio interdisciplinario de la actividad cerebral relacionada con la cognición (que incluye la percepción, el pensamiento, la memoria y el lenguaje). (pp. 13, 124)
cognitive psychology the study of mental processes, such as occur when we perceive, learn, remember, think, communicate, and solve problems. (p. 13)	**psicología cognitiva** estudio de los procesos mentales, tales como los que ocurren cuando percibimos, aprendemos, recordamos, pensamos, nos comunicamos y resolvemos problemas. (p. 13)
cognitive therapy therapy that teaches people new, more adaptive ways of thinking; based on the assumption that thoughts intervene between events and our emotional reactions. (p. 733)	**terapia cognitiva** enfoque terapéutico en que se les enseña a los pacientes nuevas formas de pensar de un modo más adaptativo. se basa en el supuesto de que los pensamientos intervienen entre los eventos y nuestras reacciones emocionales. (p. 733)
cognitive-behavioral therapy (CBT) a popular integrative therapy that combines cognitive therapy (changing self-defeating thinking) with behavior therapy (changing behavior). (p. 736)	**terapia congnitivo-conductual (CBT, en inglés)** tipo común de terapia integradora que combina la terapia cognitiva (cambia el pensamiento contraproducente) con terapia conductual (cambiar el comportamiento).
cohort a group of people sharing a common characteristic, such as from a given time period. (p. 640)	**cohorte** grupo de personas que comparten cierta característica, por ejemplo, un periodo en el tiempo. (p. 640)
collective unconscious Carl Jung's concept of a shared, inherited reservoir of memory traces from our species' history. (p. 583)	**inconsciente colectivo** concepto propuesto por Carl Jung en relación a un conjunto compartido de recuerdos heredados de la historia de nuestra especie. (p. 583)

collectivism giving priority to the goals of one’s group (often one’s extended family or work group) and defining one’s identity accordingly. (p. 616)	**colectivismo** modo de dar prioridad a las metas del grupo (a menudo de la familia extendida o el grupo de trabajo) y de definir la identidad personal a partir de lo que dicta el grupo. (p. 616)
color constancy perceiving familiar objects as having consistent color, even if changing illumination alters the wavelengths reflected by the object. (p. 192)	**constancia de color** percibir que objetos conocidos tienen un color constante, incluso cuando cambios en la iluminación modifican las longitudes de onda que el objeto refleja. (p. 192)
community psychology a branch of psychology that studies how people interact with their social environments and how social institutions affect individuals and groups. (p. 25)	**psicología comunitaria** rama de la psicología que estudia cómo las personas interactúan con sus entornos sociales y cómo las instituciones afectan a los individuos y a los grupos. (p. 25)
companionate love the deep affectionate attachment we feel for those with whom our lives are intertwined. (p. 813)	**amor compañero** apego afectuoso profundo que sentimos por aquellos con quienes nuestras vidas se entrelazan. (p. 813)
concept a mental grouping of similar objects, events, ideas, or people. (p. 365)	**concepto** agrupamiento mental de objetos, eventos, ideas y personas similares. (p. 365)
concrete operational stage in Piaget’s theory, the stage of cognitive development (from about 7 to 11 years of age) during which children gain the mental operations that enable them to think logically about concrete events. (p. 502)	**etapa del pensamiento lógico-concreto** en la teoría de Piaget, la fase del desarrollo cognitivo (aproximadamente desde los 7 hasta los 11 años de edad) durante la cual los niños adquieren las operaciones mentales que les permiten pensar lógicamente sobre eventos concretos. (p. 502)
conditioned reinforcer a stimulus that gains its reinforcing power through its association with a primary reinforcer; also known as a *secondary reinforcer*. (p. 286)	**reforzador condicionado** estímulo que obtiene sus poderes de reforzamiento a través de una asociación con un reforzador primario; también denominado reforzador secundario. (p. 286)
conditioned response (CR) in classical conditioning, a learned response to a previously neutral (but now conditioned) stimulus (CS). (p. 274)	**respuesta condicionada (rc)** en el condicionamiento clásico, la respuesta aprendida a un estímulo previamente neutral (pero ahora condicionado). (p. 274)

conditioned stimulus (CS) in classical conditioning, an originally neutral stimulus that, after association with an unconditioned stimulus (US), comes to trigger a conditioned response (CR). (p. 274)	**estímulo condicionado (ec)** en el condicionamiento clásico, un estímulo originalmente intrascendente que, después de verse asociado con un estímulo incondicionado (ei) produce una respuesta condicionada. (p. 274)
conduction hearing loss a less common form of hearing loss, caused by damage to the mechanical system that conducts sound waves to the cochlea. (p. 200)	**pérdida de la audición por conducción** tipo menos común de sordera atribuible a daños en el sistema mecánico que conduce ondas sonoras a la cóclea. (p. 200)
cones retinal receptors that are concentrated near the center of the retina and that function in daylight or in well-lit conditions. Cones detect fine detail and give rise to color sensations. (p. 178)	**conos** receptores que se concentran cerca del centro de la retina; con la luz del día o en lugares bien iluminados, los conos detectan detalles finos y producen la sensación del color. (p. 178)
confirmation bias a tendency to search for information that supports our preconceptions and to ignore or distort contradictory evidence. (p. 371)	**sesgo confirmatorio** tendencia a buscar información que confirme nuestras ideas preconcebidas y de hacer caso omiso o de distorsionar las pruebas que las contradigan. (p. 371)
conflict a perceived incompatibility of actions, goals, or ideas. (p. 819)	**conflicto** incompatibilidad percibida de acciones, metas o ideas. (p. 371)
conformity adjusting our behavior or thinking to coincide with a group standard. (p. 776)	**conformidad** tendencia a ajustar el comportamiento o la forma de pensar hasta hacerlos coincidir con las normas de un grupo. (p. 776)
confounding variable a factor other than the factor being studied that might influence a study’s results. (p. 56)	**variable de confusión** factor distinto del factor que se está estudiando que podría afectar los resultados de un estudio. (p. 56)
consciousness our subjective awareness of ourselves and our environment. (pp. 123, 224)	**consciencia** percepción de nosotros mismos y de nuestro entorno. (pp. 123, 224)
conservation the principle (which Piaget believed to be a part of concrete operational reasoning) that	**conservación** principio (que para Piaget forma parte del razonamiento operacional concreto) según el

properties such as mass, volume, and number remain the same despite changes in the forms of objects. (p. 501)	cual ciertas propiedades (ej., masa, volumen y número) no varían pese a modificaciones en la forma de los objetos. (p. 501)
content validity the extent to which a test samples the behavior that is of interest. (p. 637)	**validez del contenido** grado en que las muestras prueban el comportamiento que es de interés. (p. 637)
continuous reinforcement schedule reinforcing the desired response every time it occurs. (p. 287)	**reforzamiento continuo** reforzar la respuesta deseada cada vez que ocurre. (p. 287)
control group in an experiment, the group *not* exposed to the treatment; contrasts with the experimental group and serves as a comparison for evaluating the effect of the treatment. (p. 54)	**grupo control** en un experimento, el grupo de participantes que no se expone al tratamiento; el grupo de control sirve de comparación para evaluar el efecto del tratamiento en el grupo sometido al tratamiento. (p. 54)
convergent thinking narrowing the available problem solutions to determine the single best solution. (p. 366)	**razonamiento convergente** reducción de las soluciones disponibles con el fin de determinar cuál es la mejor solución a un problema. (p. 366)
conversion disorder a disorder related to somatic symptom disorder in which a person experiences very specific, physical symptoms that are not compatible with recognized medical or neurological conditions. (Also called functional neurological symptom disorder.) (p. 707)	**trastorno de conversión** trastorno relacionado con un trastorno de síntomas somáticos, donde una persona experimenta síntomas físicos muy específicos que no son compatibles con condiciones médicas o neurológicas reconocidas. (También conocido como trastorno de síntomas neurológicos). (p. 707)
cornea the eye’s clear, protective outer layer, covering the pupil and iris. (p. 177)	**córnea** capa protectora transparente exterior del ojo, que cubre la pupila y el iris. (p. 177)
coronary heart disease the clogging of the vessels that nourish the heart muscle; the leading cause of death in many developed countries. (p. 459)	**enfermedad coronaria** obstrucción de los vasos que nutren el músculo cardíaco; causa principal de muerte en los Estados Unidos y muchos otros países. (p. 459)
corpus callosum [KOR-pus kah-LOW-sum] the large band of neural fibers connecting the two brain hemispheres and carrying messages between them. (p. 120)	**cuerpo calloso** banda grande de fibras neuronales que conecta los dos hemisferios del cerebro y transmite mensajes entre ellos. (p. 120)

correlation a measure of the extent to which two factors vary together, and thus of how well either factor predicts the other. (p. 51)	**correlación** medida del grado en que dos factores varían juntos y por ende, si uno puede predecir al otro. (p. 51)
correlation coefficient a statistical index of the relationship between two things (from −1.00 to +1.00). (p. 51)	**coeficiente de correlación** índice estadístico de la relación entre dos cosas (del -1.00 al +1.00). (p. 51)
counseling psychology a branch of psychology that assists people with problems in living (often related to school, work, or marriage) and in achieving greater well-being. (p. 25)	**psciología de consejería** rama de la psicología que ayuda a las personas con problemas de la vida diaria (a veces relacionado con la escuela, en el trabajo, o con el matrimonio) y les ayuda a encontrar mayor bienestar. (p. 25)
counterconditioning behavior therapy procedures that use classical conditioning to evoke new responses to stimuli that are triggering unwanted behaviors; include *exposure therapies* and *aversive conditioning*. (p. 729)	**contracondicionamiento** técnicas de terapia conductual que se valen del condicionamiento clásico para provocar respuestas alternativas a estímulos que producen comportamientos no deseados; incluye las terapias de exposición y el condicionamiento aversivo. (p. 729)
creativity the ability to produce new and valuable ideas. (p. 366)	**creatividad** capacidad para generar ideas novedosas y valiosas. (p. 636)
critical period an optimal period early in the life of an organism when exposure to certain stimuli or experiences produces normal development. (p. 510)	**período crítico** etapa inicial de la vida de los organismos, en la cual son necesarios ciertos estímulos o experiencias para permitir su desarrollo normal. (p. 510)
critical thinking thinking that does not blindly accept arguments and conclusions. Rather, it examines assumptions, appraises the source, discerns hidden biases, evaluates evidence, and assesses conclusions. (p. 4)	**pensamiento crítico** forma de pensar que no admite razones ni conclusiones ciegamente. En cambio, se evalúan las fuentes, se buscan los sesgos ocultos, se analiza la evidencia y se estudian las conclusiones. (p. 4)
cross-sectional study research that compares people of different ages at the same point in time. (pp. 563, 640)	**estudio de corte transversal** estudio en el que personas de diferentes edades se comparan unas con otras en un mismo punto en el tiempo. (pp. 563, 640)
crystallized intelligence	**inteligencia cristalizada**

our accumulated knowledge and verbal skills; tends to increase with age. (p. 640)	todos los conocimientos y capacidades verbales que acumulamos; tiende a aumentar con la edad. (p. 640)
CT (computed tomography) scan a series of X-ray photographs taken from different angles and combined by computer into a composite representation of a slice of the brain’s structure. (Also called CAT scan.) (p. 99)	**TC (tomografía computarizada)** serie de imágenes de rayos-X tomadas desde ángulos distintos y combinadas por computadora para formar una representación compuesta de un corte de la estructura cerebral (conocida también cono exploración TAC). (p. 99)
culture the enduring behaviors, ideas, attitudes, values, and traditions shared by a group of people and transmitted from one generation to the next. (pp. 15, 789)	**cultura** ideas, actitudes, valores y tradiciones preponderantes compartidas por un grupo de personas y que se transmiten de generación en generación. (pp. 15, 789)
D	
debriefing the postexperimental explanation of a study, including its purpose and any deceptions, to its participants. (p. 62)	**rendición de informes** explicación que se les da a los participantes de un estudio sobre sus fines y los posibles engaños que los investigadores pudieron haber utilizado. (p. 62)
deep processing encoding semantically, based on the meaning of the words; tends to yield the best retention. (p. 335)	**procesamiento profundo** codificación semántica basada en el significado de las palabras; suele ser ideal para la retención. (p. 335)
defense mechanisms in psychoanalytic theory, the ego’s protective methods of reducing anxiety by unconsciously distorting reality. (p. 581)	**mecanismos de defensa** en la teoría del psicoanálisis, los métodos de protección del ego para reducir la ansiedad mediante la distorsión inconsciente de la realidad. (p. 581)
deindividuation the loss of self-awareness and self-restraint occurring in group situations that foster arousal and anonymity. (p. 786)	**desindividualización** pérdida de la identidad personal y del autocontrol en situaciones de grupo que fomentan la excitación y el anonimato. (p. 786)
déjà vu that eerie sense that “I’ve experienced this before.” Cues from the current situation may unconsciously trigger retrieval of an earlier experience. (p. 358)	***déjà vu*** sensación extraña de haber vivido antes una experiencia específica. Ciertas pistas del presente inmediato pueden evocar una vivencia previa. (p. 358)

delta waves the large, slow brain waves associated with the deep sleep of NREM-3. (p. 234)	**ondas delta** ondas cerebrales grandes y lentas asociadas con el sueño profundo tipo NMOR. (p. 234)
delusion a false belief, often of persecution or grandeur, that may accompany psychotic disorders. (p. 699)	**delirio** creencias falsas, a menudo de persecución o de grandeza que pueden acompañar a trastornos psicóticos. (p. 699)
dendrites a neuron’s often bushy, branching extensions that receive and integrate messages, conducting impulses toward the cell body. (p. 82)	**dendritas** prolongaciones de las neuronas que reciben mensajes y envían impulsos hacia el cuerpo neuronal. (p. 82)
dependent variable in an experiment, the outcome that is measured; the variable that may change when the independent variable is manipulated. (p. 56)	**variable dependiente** el valor que se mide en un experimento;. es la variable que puede cambiar cuando se manipula la variable independiente. (p. 56)
depressants drugs (such as alcohol, barbiturates, and opiates) that reduce neural activity and slow body functions. (p. 255)	**depresivos** agentes químicos (como el alcohol, los barbitúricos y los opioides) que reducen (deprimen) la actividad neuronal y disminuyen las funciones del organismo. (p. 255)
depth perception the ability to see objects in three dimensions although the images that strike the retina are two-dimensional; allows us to judge distance. (p. 189)	**percepción de la profundidad** capacidad de ver objetos en tres dimensiones aún cuando las imágenes percibidas por la retina son bidimensionales. Nos permite juzgar la distancia. (p. 189)
descriptive statistics numerical data used to measure and describe characteristics of groups. Includes measures of central tendency and measures of variation. (p. 66)	**estadística descriptiva** datos numéricos que se usan para medir y describir características de grupos. Incluye medidas de tendencia central y medidas de variación. (p. 66)
developmental psychology a branch of psychology that studies physical, cognitive, and social change throughout the life span. (pp. 24, 486)	**psicología del desarrollo** rama de la psicología que estudia los cambios físicos, cognitivos y sociales que ocurren a lo largo de la vida. (pp. 24, 486)
difference threshold the minimum difference between two stimuli required for detection 50 percent of the time.	**umbral de diferencia** la diferencia mínima entre dos estímulos que una persona puede detectar el 50 por ciento

We experience the difference threshold as a *just noticeable difference* (or *jnd*). (p. 163)	de las veces. El umbral diferencial se experimenta como una *diferencia apenas perceptible* (o *jnd*, en inglés). (p. 163)
discrimination (1) in classical conditioning, the learned ability to distinguish between a conditioned stimulus and similar stimuli that do not signal an unconditioned stimulus. (In operant conditioning, the ability to distinguish responses that are reinforced from similar responses that are not reinforced.) (2) in social psychology, unjustifiable negative behavior toward a group and its members. (pp. 277, 792)	**discriminación** (1) según el condicionamiento clásico, es la capacidad aprendida de distinguir entre un estímulo condicionado y otros estímulos sin trascendencia. (en el condicionamiento operante, la capacidad de distinguir las respuestas que son reforzadas de las que no lo son). (2) en psicología social, comportamiento negativo injustificado contra un grupo y sus miembros. (pp. 277, 792)
discriminative stimulus in operant conditioning, a stimulus that elicits a response after association with reinforcement (in contrast to related stimuli not associated with reinforcement). (p. 285)	**estímulo discriminativo** en el condicionamiento operante, un estímulo que genera una respuesta después de ser asociado con un reforzamiento (en contraste con estímulos relacionados que no están asociados con un reforzamiento). (p. 285)
dissociation a split in consciousness, which allows some thoughts and behaviors to occur simultaneously with others. (p. 227)	**disociación** una apertura en el conocimiento consciente que permite que algunos pensamientos y comportamientos ocurran en forma simultánea con otros. (p. 227)
dissociative disorders controversial, rare disorders in which conscious awareness becomes separated (dissociated) from previous memories, thoughts, and feelings. (p. 708)	**trastornos disociativos** trastornos poco comunes, polémicos y controvertidos en los cuales el conocimiento consciente se separa (si desasocia) de recuerdos, pensamientos y sentimientos previos. (p. 708)
dissociative identity disorder (DID) a rare dissociative disorder in which a person exhibits two or more distinct and alternating personalities. (Formerly called *multiple personality disorder*.) (p. 708)	**trastorno disociativo de identidad (TDI)** trastorno disociativo poco común, en el cual una persona exhibe dos o más personalidades claramente definidas que se alternan entre sí. (También se denomina trastorno de *personalidad múltiple*) (p. 708)
divergent thinking expanding the number of possible problem solutions; creative thinking that diverges in different directions. (p. 366)	**razonamiento divergente** expansión del número de soluciones a un problema. Pensamiento creativo que se ramifica en múltiples direcciones. (p. 366)

DNA (deoxyribonucleic acid) a complex molecule containing the genetic information that makes up the chromosomes. (p. 130)	**ADN (ácido desoxirribonucleico)** molécula compleja que contiene la información genética de la que se constituyen los cromosomas. (p. 130)
double-blind procedure an experimental procedure in which both the research participants and the research staff are ignorant (blind) about whether the research participants have received the treatment or a placebo. Commonly used in drug-evaluation studies. (p. 55)	**procedimiento doble ciego** en un experimento, procedimiento en el cual tanto los participantes como el personal de investigación ignoran (van a ciegas) quién ha recibido el tratamiento y quién el placebo. (p. 55)
Down syndrome a condition of mild to severe intellectual disability and associated physical disorders caused by an extra copy of chromosome 21. (p. 644)	**síndrome de Down** trastorno de discapacidad intelectual leve o grave que se presenta junto a otras discapacidades físicas que ocurren a causa de una copia adicional del cromosoma 21. (p. 644)
dream a sequence of images, emotions, and thoughts passing through a sleeping person's mind. (p. 247)	**sueño** secuencia de imágenes, emociones y pensamientos que fluyen en la mente de una persona dormida. (p. 247)
drive-reduction theory the idea that a physiological need creates an aroused state (a drive) that motivates an organism to satisfy the need. (p. 403)	**teoría de la reducción del impulso** concepto según el cual una necesidad fisiológica crea un estado de excitación (un impulso) que motiva al organismo a satisfacer tal necesidad. (p. 403)
DSM-5 the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition; a widely used system for classifying psychological disorders. (p. 669)	**DSM-5** *Manual estadístico y de diagnóstico de trastornos mentales*, de la Asociación Norteamericana de Psiquiatría, quinta edición. Sistema ampliamente utilizado para clasificar los trastornos psicológicos. (p. 669)
dual processing the principle that information is often simultaneously processed on separate conscious and unconscious tracks. (p. 125)	**procesamiento dual** principio que sostiene que la información se procesa simultáneamente en vías separadas conscientes e inconscientes. (p. 125)
E	
echoic memory a momentary sensory memory of auditory stimuli; if attention is elsewhere, sounds and	**memoria ecoica** memoria sensorial momentánea de estímulos auditivos; aún cuando uno no presta

words can still be recalled within 3 or 4 seconds. (p. 332)	atención, es posible recordar palabras por 3 o 4 segundos. (p. 332)
eclectic approach an approach to psychotherapy that uses techniques from various forms of therapy. (p. 723)	**enfoque ecléctico** enfoque de psicoterapia que emplea técnicas de varias formas de terapia. (p. 723)
Ecstasy (MDMA) a synthetic stimulant and mild hallucinogen. Produces euphoria and social intimacy, but with short-term health risks and longer-term harm to serotonin-producing neurons and to mood and cognition. (p. 261)	**éxtasis (MDMA)** estimulante sintético que produce un ligero efecto alucinógeno. Produce euforia e intimidad social, pero con riesgos de corto plazo para la salud y daños a largo plazo para el ánimo, para el proceso de cognición y para las neuronas productoras de serotonina. (p. 261)
educational psychology the study of how psychological processes affect and can enhance teaching and learning. (p. 24)	**psicología educativa** el estudio de cómo los procesos psicológicos afectan y mejoran la enseñanza y el aprendizaje. (p. 24)
EEG (electroencephalogram) an amplified recording of the waves of electrical activity sweeping across the brain's surface. These waves are measured by electrodes placed on the scalp. (p. 99)	**EEG (electroencefalograma)** el registro de las ondas de actividad eléctrica que circulan por la superficie del cerebro. Las ondas se miden a través de electrodos colocados sobre el cuero cabelludo. (p. 99)
effortful processing encoding that requires attention and conscious effort. (p. 330)	**procesamiento con esfuerzo** codificación que requiere de atención y esfuerzo conscientes. (p. 33)
ego the largely conscious, "executive" part of personality that, according to Freud, mediates among the demands of the id, superego, and reality. The ego operates on the *reality principle*, satisfying the id's desires in ways that will realistically bring pleasure rather than pain. (p. 580)	**ego** entre las exigencias del id, el superego y la realidad. El ego opera según el *principio de realidad*, para satisfacer los deseos del id en formas que de manera realista le brindarían placer en lugar de dolor. (p. 580)
egocentrism in Piaget's theory, the preoperational child's difficulty taking another's point of view. (p. 501)	**egocentrismo** según la teoría de Piaget, la dificultad de los niños en la etapa preoperacional para aceptar un punto de vista ajeno. (p. 501)
electroconvulsive therapy (ECT)	**terapia electroconvulsiva (TEC)**

a biomedical therapy for severely depressed patients in which a brief electric current is sent through the brain of an anesthetized patient. (p. 756)	terapia biomédica para pacientes gravemente deprimidos en la que se envía una corriente eléctrica de corta duración a través del cerebro de un paciente anestesiado. (p. 756)
embodied cognition the influence of bodily sensations, gestures, and other states on cognitive preferences and judgments. (p. 214)	**cognición incorporada** la influencia de sensaciones del organismo, y otros estados sobre las preferencias y juicios cognitivos. (p. 214)
embryo the developing human organism from about 2 weeks after fertilization through the second month. (p. 489)	**embrión** etapa de desarrollo del organismo humano a partir de las dos semanas después de fertilización hasta el segundo mes. (p. 489)
emerging adulthood a period from about age 18 to the mid-twenties, when many in Western cultures are no longer adolescents but have not yet achieved full independence as adults. (p. 542)	**madurez emergente** etapa que se extiende desde los 18 hasta alrededor de los 25 años, durante la cual muchas personas en los países occidentales ya no son adolescentes pero aún no han alcanzado la independencia plena de un adulto. (p. 542)
emotion a response of the whole organism, involving (1) physiological arousal, (2) expressive behaviors, and (3) conscious experience. (p. 433)	**emoción** reacción que involucra a todo el organismo e incluye (1) excitación fisiológica, (2) comportamientos expresivos y (3) experiencia consciente. (p. 433)
emotion-focused coping attempting to alleviate stress by avoiding or ignoring a stressor and attending to emotional needs related to our stress reaction. (p. 306)	**superación con enfoque en las emociones** medidas para sobrellevar las tensiones enfocándose en aliviar o hacer caso omiso de una situación estresante y atender las necesidades emocionales relacionadas con nuestra reacción al estrés. (p. 306)
emotional intelligence the ability to perceive, understand, manage, and use emotions. (p. 629)	**inteligencia emocional** capacidad de percibir, entender, administrar y hacer uso de las emociones. (p. 629)
empirically derived test a test (such as the MMPI) created by selecting from a pool of items those that discriminate between groups. (p. 599)	**prueba empírica** una prueba (por ejemplo, la MMPI) creada al seleccionar, de un conjunto de elementos, a aquellos que discriminan entre grupos. (p. 599)
empiricism	**empirismo**

the idea that knowledge comes from experience, and that observation and experimentation enable scientific knowledge. (p. 7)	idea según la cual el conocimiento nace de la experiencia y la observación y la experimentación habilitan el conocimiento científico. (p. 7)
encoding specificity principle the idea that cues and contexts specific to a particular memory will be most effective in helping us recall it. (p. 345)	**principio de especificidad de codificación** idea según la cual las pistas y los contextos específicos de un recuerdo particular serán las más efectivas para ayudarnos a recordarlo. (p. 345)
encoding the process of getting information into the memory system— for example, by extracting meaning. (p. 329)	**codificación** el proceso de ingresar información al sistema de memoria; por ejemplo, mediante la extracción de significado. (p. 329)
endocrine [EN-duh-krin] **system** the body's "slow" chemical communication system; a set of glands that secrete hormones into the bloodstream. (p. 95)	**sistema endócrino** sistema "lento" de comunicación química del cuerpo; conjunto de glándulas que secretan hormonas al torrente sanguíneo. (p. 95)
endorphins [en-DOR-fins] "morphine within"—natural, opiate-like neurotransmitters linked to pain control and to pleasure. (p. 88)	**endorfinas** "morfina interna"; neurotransmisores naturales similares a los opiáceos que están asociados con el control del dolor y con el placer. (p. 88)
environment every nongenetic influence, from prenatal nutrition to the people and things around us. (p. 129)	**entorno** toda influencia externa, desde la alimentación prenatal hasta el apoyo social que se recibe más adelante en la vida. (p. 129)
epigenetics "above" or "in addition to" *(epi)* genetics; the study of environmental influences on gene expression that occur without a DNA change. (pp. 137, 668)	**epigenética** "encima de" o "además de" (*epi*) genética; estudio de la influencia ambiental sobre la expresión de los genes que ocurre sin un cambio de ADN. (pp. 137, 668)
episodic memory explicit memory of personally experienced events; one of our two conscious memory systems (the other is *semantic memory*). (p. 340)	**memoria episódica** memoria explícita de eventos experimentados personalmente. Uno de los dos sistemas de memoria conscientes (el otro es la *memoria semántica*). (p. 340)
equity a condition in which people receive from a	**equidad** condición en la cual la persona recibe de

relationship in proportion to what they give to it. (p. 813)	manera proporcional lo que aporta a una relación. (p. 813)
estrogens sex hormones, such as estradiol, that contribute to female sex characteristics and are secreted in greater amounts by females than by males. Estrogen levels peak during ovulation. In nonhuman mammals, this promotes sexual receptivity. (p. 418)	**estrógenos** hormonas sexuales, como el estradiol, secretadas en mayor cantidad en la mujer que en el hombre. Los niveles de estrógeno alcanzan su nivel máximo durante la ovulación. En los animales mamíferos esto facilita la receptividad sexual. (p. 418)
evidence-based practice clinical decision making that integrates the best available research with clinical expertise and patient characteristics and preferences. (p. 744)	**práctica basada en la evidencia** toma de decisiones clínicas que integra lo mejor de las investigaciones disponibles con la especialización clínica y las características y preferencias del paciente. (p. 744)
evolutionary psychology the study of the evolution of behavior and the mind, using principles of natural selection. (pp. 14, 141)	**psicología evolutiva** estudio de la evolución del comportamiento y la mente, que emplea los principios de la selección natural. (pp. 14, 141)
experiment a research method in which an investigator manipulates one or more factors (independent variables) to observe the effect on some behavior or mental process (the dependent variable). By *random assignment* of participants, the experimenter aims to control other relevant factors. (p. 54)	**experimento** método de investigación en el cual el investigador manipula uno o más factores (variables independientes) para observar su efecto en un comportamiento o proceso mental (variable dependiente). Al ser los participantes *asignados de manera aleatoria*, los investigadores procuran controlar otros factores relevantes. (p. 54)
experimental group in an experiment, the group exposed to the treatment, that is, to one version of the independent variable. (p. 54)	**grupo experimental** sujetos de un experimento que están expuestos al tratamiento, o sea, a una versión de la variable independiente. (p. 54)
explicit memory retention of facts and experiences that one can consciously know and “declare.” (Also called *declarative memory*.) (p. 330)	**memoria explícita** retención de hechos y vivencias personales que tenemos la capacidad de reconocer y “expresar” conscientemente. También se le dice *memoria declarativa*. (p. 330)
exposure therapies behavioral techniques, such as *systematic desensitization* and *virtual reality exposure therapy*, that treat anxieties by exposing	**terapias de exposición** técnicas conductuales, como la *desensibilización sistemática* y la *terapia de exposición a una realidad virtual* para tratar

people (in imaginary or actual situations) to the things they fear and avoid. (p. 730)	la ansiedad exponiendo a la persona (en situaciones imaginarias o reales) a las cosas que teme y evita. (p. 730)
external locus of control the perception that chance or outside forces beyond our personal control determine our fate. (p. 309)	**centro de control externo** impresión de que nuestro destino está determinado por el azar o por fuerzas que están más allá de nuestro control. (p. 309)
extinction the diminishing of a conditioned response; occurs in classical conditioning when an unconditioned stimulus (US) does not follow a conditioned stimulus (CS); occurs in operant conditioning when a response is no longer reinforced. (p. 276)	**extinción** disminución de una respuesta condicionada; sucede en el condicionamiento clásico cuando un estímulo incondicionado no sigue a un estímulo condicionado; en el condicionamiento operante, disminución de una respuesta cuando deja de ser reforzada. (p. 276)
extrasensory perception (ESP) the controversial claim that perception can occur apart from sensory input; includes telepathy, clairvoyance, and precognition. (p. 172)	**percepción extrasensorial (PES)** la afirmación polémica de que la percepción puede ocurrir aislada de la recepción sensorial; incluye la telepatía, la clarividencia y las premoniciones. (p. 172)
extrinsic motivation a desire to perform a behavior to receive promised rewards or avoid threatened punishment. (p. 305)	**motivación extrínseca** deseo de llevar a cabo un comportamiento para obtener una recompensa o evitar el castigo. (p. 305)
F	
facial feedback effect the tendency of facial muscle states to trigger corresponding feelings such as fear, anger, or happiness. (p. 447)	**efecto de reacción facial** tendencia de los músculos faciales a provocar sentimientos correspondientes como el miedo, el enojo o la felicidad. (p. 447)
factor analysis a statistical procedure that identifies clusters of related items (called factors) on a test; used to identify different dimensions of performance that underlie a person's total score. (p. 626)	**análisis de factores** procedimiento estadístico que identifica conjuntos de artículos relacionados (conocidos como factores) en una prueba; se usa para identificar distintas dimensiones del desempeño que subyace el puntaje total de una persona. (p. 626)
family therapy therapy that treats people in the context of their family system. Views an individual's unwanted behaviors as influenced by, or	**terapia de familia** tipo de terapia que trata a las personas en el contexto de su sistema familiar. Esta terapia considera que los comportamientos no

directed at, other family members. (p. 737)	deseados de una persona son influenciados por otros miembros de la familia o están dirigidos hacia ellos. (p. 737)
feature detectors nerve cells in the brain’s visual cortex that respond to specific features of the stimulus, such as shape, angle, or movement. (p. 183)	**detectores específicos** células nerviosas del cerebro que responden a características específicas de un estímulo, como las formas, los ángulos y el movimiento. (p. 183)
feel-good, do-good phenomenon people’s tendency to be helpful when in a good mood. (p. 473)	**fenómeno de sentirse bien y hacer el bien** tendencia a ayudar a los demás cuando estamos de buen humor. (p. 473)
fetal alcohol syndrome (FAS) physical and cognitive abnormalities in children caused by a pregnant woman’s heavy drinking. In severe cases, signs include a small, out-of-proportion head and abnormal facial features. (p. 490)	**síndrome de alcoholismo fetal (SAF)** anomalías físicas y cognitivas en los niños causadas por la intensa ingestión de alcohol de la madre durante el embarazo. En casos agudos, los síntomas incluyen desproporciones en el tamaño de la cabeza, que puede ser demasiado pequeña y rasgos faciales anormales. (p. 490)
fetus the developing human organism from 9 weeks after conception to birth. (p. 489)	**feto** organismo humano en vías de desarrollo desde las 9 semanas de concepción hasta el nacimiento. (p. 489)
figure-ground the organization of the visual field into objects (the *figures*) that stand out from their surroundings (the *ground*). (p. 187)	**figura-trasfondo** organización del campo visual en objetos (*las figuras*) que se distinguen de sus entornos (*los trasfondos*). (p. 187)
fixation (1) in cognition, the inability to see a problem from a new perspective; an obstacle to problem solving. (2) in personality theory, according to Freud, a lingering focus of pleasure-seeking energies at an earlier psychosexual stage, in which conflicts were unresolved. (pp. 371, 581)	**fijación** (1) en términos cognitivos la incapacidad de ver un problema desde una perspectiva nueva; un impedimento para resolver problemas. (2) en la teoría de la personalidad, según Freud, un foco persistente de energías en busca del placer en una etapa psicosexual anterior en la que los conflictos todavía no estaban resueltos. (pp. 371, 581)
fixed-interval schedule in operant conditioning, a reinforcement schedule that reinforces a response only after a specified time has elapsed. (p. 288)	**cronograma de intervalo fijo** según el condicionamiento operante, cronograma de reforzamiento que refuerza la respuesta solo después de haber transcurrido un tiempo específico. (p. 288)

fixed-ratio schedule in operant conditioning, a reinforcement schedule that reinforces a response only after a specified number of responses. (p. 288)	**cronograma de proporción fija** según el condicionamiento operante, cronograma de reforzamiento que refuerza la respuesta solo después de darse un número específico de respuestas. (p. 288)
flashbulb memory a clear, sustained memory of an emotionally significant moment or event. (p. 342)	**memoria de flash** memoria clara de un momento o evento emocionalmente significativo. (p. 342)
fluid intelligence our ability to reason speedily and abstractly; tends to decrease with age, especially during late adulthood. (p. 640)	**inteligencia fluida** nuestra capacidad para razonar de manera rápida y abstracta; tiende a disminuir con la edad, especialmente en la vejez. (p. 640)
fMRI (functional MRI) a technique for revealing bloodflow and, therefore, brain activity by comparing successive MRI scans. fMRI scans show brain function as well as structure. (p. 100)	**IRMf (imagen de resonancia magnética funcional)** técnica para observar la circulación de la sangre y, por lo tanto, la actividad cerebral mediante la comparación de imágenes de resonancia magnética sucesivas. Las imágenes de resonancia magnética funcional muestran el funcionamiento del cerebro. (p. 100)
foot-in-the-door phenomenon the tendency for people who have first agreed to a small request to comply later with a larger request. (p. 771)	**fenómeno del pie en la puerta** tendencia de la gente a acceder primero a una solicitud menor para después acceder a una solicitud más significativa. (p. 771)
formal operational stage in Piaget’s theory, the stage of cognitive development (normally beginning about age 12) during which people begin to think logically about abstract concepts. (p. 502)	**período operacional formal** en la teoría de Piaget, el período en el desarrollo cognitivo (normalmente empieza a los 12 años) durante el que la persona empieza a pensar lógicamente sobre conceptos abstractos. (p. 502)
fovea the central focal point in the retina, around which the eye’s cones cluster. (p. 179)	**fovea** el punto central de enfoque en la retina, alrededor del cuál se agrupan los conos del ojo. (p. 179)
framing the way an issue is posed; how an issue is worded can significantly affect decisions and judgments. (p. 376)	**encuadre** forma en que se presenta un asunto; el encuadre puede influir considerablemente en las decisiones y las opiniones. (p. 376)

fraternal (dizygotic) twins develop from separate fertilized eggs. They are genetically no closer than ordinary brothers and sisters, but they share a prenatal environment. (p. 132)	**gemelos fraternos (dizigóticos)** se desarrollan de dos óvulos fecundados. Genéticamente no son más cercanos que los hermanos y hermanas, pero comparten un entorno prenatal. (p. 132)
free association in psychoanalysis, a method of exploring the unconscious in which the person relaxes and says whatever comes to mind, no matter how trivial or embarrassing. (p. 579)	**asociación libre** en psicoanálisis, método de explorar el inconsciente en el que la persona se relaja y dice lo primero que le viene a la mente, sin importar si es poco importante o incómodo. (p. 579)
frequency the number of complete wavelengths that pass a point in a given time (for example, per second). (p. 198)	**frecuencia** número de ondas completas que pasan un punto en un tiempo dado (por ejemplo, por segundo). (p. 198)
frequency theory in hearing, the theory that the rate of nerve impulses traveling up the auditory nerve matches the frequency of a tone, thus enabling us to sense its pitch. (Also called *temporal theory*.) (p. 202)	**teoría de frecuencias** en la audición, la teoría según la cual la tasa de impulsos nerviosos que viajan por el nervio auditivo coincide con la frecuencia de un tono, lo cual nos permite percibir su tono. (Se conoce también como teoría *temporal*) (p. 202)
frontal lobes the portion of the cerebral cortex lying just behind the forehead; involved in speaking and muscle movements and in making plans and judgments. (p. 109)	**lóbulos frontales** porción de la corteza cerebral que se halla inmediatamente detrás de la frente; se relaciona con el habla y los movimientos musculares y con la planificación y la formación de juicios. (p. 109)
frustration-aggression principle the principle that frustration—the blocking of an attempt to achieve some goal—creates anger, which can generate aggression. (p. 803)	**principio de frustración-agresión** principio según el cual la frustración —el bloqueo de un intento para lograr alguna meta— crea ira, y por consecuencia puede generar agresión. (p. 803)
functionalism an early school of thought promoted by James and influenced by Darwin; explored how mental and behavioral processes function—how they enable the organism to adapt, survive, and flourish. (p. 8)	**funcionalismo** escuela temprana de pensamiento promovida por James e influenciada por Darwin; exploró el funcionamiento de los procesos mentales y conductuales–y cómo habilitan al organismo para adaptarse, sobrevivir y florecer. (p. 8)
fundamental attribution error	**error de atribución fundamental**

the tendency for observers, when analyzing others' behavior, to underestimate the impact of the situation and to overestimate the impact of personal disposition. (p. 768)	tendencia de los observadores, cuando analizan el comportamiento ajeno, a sobrestimar el impacto de la situación y sobreestimar el impacto de la disposición personal. (p. 768)
G	
gate-control theory the theory that the spinal cord contains a neurological "gate" that blocks pain signals or allows them to pass on to the brain. The "gate" is opened by the activity of pain signals traveling up small nerve fibers and is closed by activity in larger fibers or by information coming from the brain. (p. 207)	**teoría de la compuerta** teoría según la cual la médula espinal contiene una "compuerta neurológica" que bloquea señales de dolor o permite que lleguen al cerebro. La "compuerta" se abre con la actividad de señales de dolor que viajan por fibras nerviosas pequeñas y se cierra con la actividad de fibras más grandes o con información que llega del cerebro. (p. 207)
gender identity our sense of being male, female, or some combination of the two. (p. 525)	**identidad de género** nuestra sensación personal de ser varón o mujer, o combinación de ambas. (p. 525)
gender in psychology, the socially influenced characteristics by which people define *boy, girl, man,* and *woman*. (p. 520)	**género** en la psicología las características sociales que las personas emplean para definir *niño, niña, hombre* y *mujer*. (p. 520)
gender role a set of expected behaviors, attitudes, and traits for males or for females. (p. 525)	**papel de género** conjunto de expectativas, actitudes y rasgos de cómo las mujeres y los hombres deben ser o comportarse. (p. 525)
gender typing the acquisition of a traditional masculine or feminine role. (p. 525)	**tipificación por género** la adquisición de un papel masculino o femenino tradicional. (p. 525)
general adaptation syndrome (GAS) Selye's concept of the body's adaptive response to stress in three phases—alarm, resistance, exhaustion. (p. 454)	**síndrome de adaptación general** término usado por Selye para referirse a la respuesta adaptiva del cuerpo ante estrés, que se da en tres etapas: alarma, resistencia y agotamiento. (p. 454)
general intelligence (g) according to Spearman and others, underlies all mental abilities and is therefore measured by every task on an intelligence test. (p. 626)	**factor g de inteligencia general** según Spearman y otros, subyace todas las habilidades mentales específicas y es, por tanto, cuantificado por cada función en una prueba de inteligencia. (p. 626)

generalization the tendency, once a response has been conditioned, for stimuli similar to the conditioned stimulus to elicit similar responses. (In operant conditioning, generalization occurs when responses learned in one situation occur in other, similar situations.) (p. 276)	**generalización** según el condicionamiento clásico, tendencia posterior al condicionamiento, de responder de manera similar a los estímulos que se parecen al estímulo condicionado. (En el condicionamiento operante, se produce una generalización cuando se refuerzan también las respuestas a estímulos similares.) (p. 276)
generalized anxiety disorder an anxiety disorder in which a person is continually tense, apprehensive, and in a state of *autonomic nervous system* arousal. (p. 677)	**trastorno de ansiedad general** trastorno de ansiedad en el cual una persona está constantemente tensa, asustada y con el *sistema nervioso autónomo* activado. (p. 677)
genes the biochemical units of heredity that make up the chromosomes; segments of DNA capable of synthesizing proteins. (p. 130)	**genes** unidades bioquímicas de la herencia que forman los cromosomas; segmentos de DNA capaces de sintetizar proteínas. (p. 130)
genome the complete instructions for making an organism, consisting of all the genetic material in that organism's chromosomes. (p. 130)	**genoma** instrucciones completas para crear un organismo; consiste en todo el material genético en los cromosomas de ese organismo. (p. 130)
gestalt an organized whole. Gestalt psychologists emphasized our tendency to integrate pieces of information into meaningful wholes. (p. 187)	**Gestalt** un todo organizado. Los psicólogos de la Gestalt enfatizan nuestra tendencia a integrar segmentos de información en organismos únicos significativos. (p. 187)
glial cells (glia) cells in the nervous system that support, nourish, and protect neurons; they also play a role in learning, thinking, and memory. (p. 82)	**células gliales** células del sistema nervioso que apoyan, alimentan y protegen a las neuronas; también desempeñan un papel en el aprendizaje, el razonamiento y la memoria. (p. 82)
glucose the form of sugar that circulates in the blood and provides the major source of energy for body tissues. When its level is low, we feel hunger. (p. 409)	**glucosa** forma de azúcar que circula en la sangre y es la mayor fuente de energía para los tejidos del cuerpo. Cuando baja su nivel, sentimos hambre. (p. 409)
grammar in a language, a system of rules that enables us to communicate with and understand others. *Semantics* is the language's set of	**gramática** en un lenguaje específico, sistema de reglas que nos permite comunicarnos y entendernos con otros. La *semántica* es el conjunto de

rules for deriving meaning from sounds, and *syntax* is its set of rules for combining words into grammatically sensible sentences. (p. 382)	reglas del lenguaje para derivar significados a partir de sonidos, y la *sintaxis* es el conjunto de reglas para combinar palabras en oraciones gramáticamente sensibles. (p. 382)
GRIT Graduated and Reciprocated Initiatives in Tension- Reduction—a strategy designed to decrease international tensions. (p. 822)	**GRIT Iniciativas Graduadas y Recíprocas en Reducción de Tensión (Graduated and Reciprocated Initiatives in Tension-Reduction)** estrategia diseñada para reducir tensiones internacionales. (p. 822)
grit in psychology, passion and perseverance in the pursuit of long-term goals. (pp. 429, 629)	**tenacidad** en psicología, se refiere a la pasión y la perseverancia en la búsqueda de objetivos a largo plazo (pp. 429, 629)
group polarization the enhancement of a group’s prevailing inclinations through discussion within the group. (p. 787)	**efecto de polarización de grupo** solidificación y fortalecimiento de las posiciones imperantes en un grupo mediante diálogos en el grupo. (p. 787)
group therapy therapy conducted with groups rather than individuals, providing benefits from group interaction. (p. 737)	**terapia de grupo** tratamiento que se realiza con grupos en lugar de con personas individuales, y que genera beneficios de la interacción del grupo. (p. 737)
grouping the perceptual tendency to organize stimuli into coherent groups. (p. 188)	**agrupamiento** tendencia de percepción que clasifica los estímulos en grupos que tienen sentido. (p. 188)
groupthink the mode of thinking that occurs when the desire for harmony in a decision-making group overrides a realistic appraisal of alternatives. (p. 788)	**pensamiento colectivo** modo de pensar que ocurre cuando el deseo de armonía en un grupo que toma de decisiones colectivas anula la evaluación objetiva de las alternativas. (p. 788)
H	
habituation decreasing responsiveness with repeated exposure to a stimulus. (pp. 271, 491)	**aclimatación** reducir el nivel de respuesta al ser expuesto repetidamente a un estímulo. (pp. 271, 491)
hallucinations false sensory experiences, such as seeing something in the absence of an external	**alucinaciones** vivencia sensorial falsa, por ejemplo, cuando una persona ve algo sin haber ningún

visual stimulus. (pp. 233, 699)	estímulo visual externo. (pp. 233, 699)
hallucinogens psychedelic (“mind-manifesting”) drugs, such as LSD, that distort perceptions and evoke sensory images in the absence of sensory input. (p. 261)	**alucinógenos** fármacos psicodélicos (“que se manifiestan en la mente”), como el LSD, que distorsionan las percepciones y desencadenan imágenes sensoriales sin la intervención de estímulos sensoriales. (p. 261)
health psychology a subfield of psychology that provides psychology’s contribution to behavioral medicine. (p. 456)	**psicología de la salud** área de la psicología que brinda la contribución de la psicología a la medicina del comportamiento. (p. 456)
heredity the genetic transfer of characteristics from parents to offspring. (p. 129)	**herencia** transferencia genética de características, de los padres a los hijos. (p. 129)
heritability the proportion of variation among individuals in a group that we can attribute to genes. The heritability of a trait may vary, depending on the range of populations and environments studied. (pp. 135, 647)	**heredabilidad** la proporción de variación entre individuos que le podemos atribuir a los genes. La heredabilidad de un rasgo varía de acuerdo con la población y el medio ambiente. (pp. 135, 647)
heuristic a simple thinking strategy that often allows us to make judgments and solve problems efficiently; usually speedier but also more errorprone than an *algorithm*. (p. 370)	**heurística** estrategia de pensamiento sencilla que a menudo nos permite formar juicios y resolver problemas de manera eficiente; en general es más expedita que utilizar *algoritmos*, pero también hay mayor propensión a errores. (p. 370)
hierarchy of needs Maslow’s pyramid of human needs, beginning at the base with physiological needs that must first be satisfied before higher-level safety needs and then psychological needs become active. (pp. 405, 591)	**jerarquía de necesidades** la pirámide de Maslow de las necesidades humanas comienza con las necesidades fisiológicas, que deben satisfacerse antes que las necesidades de seguridad personal que son de más alto nivel. Las necesidades psicológicas son las últimas en activarse, después de satisfacer las anteriores. (pp. 405, 591)
higher-order conditioning a procedure in which the conditioned stimulus in one conditioning experience is paired with a new neutral stimulus, creating	**condicionamiento de orden superior** procedimiento donde se junta un estímulo condicionado de una experiencia de condicionamiento con un estímulo neutral,

a second (often weaker) conditioned stimulus. For example, an animal that has learned that a tone predicts food might then learn that a light predicts the tone and begin responding to the light alone. (Also called *second-order conditioning*.) (p. 276)	que crea un segundo estímulo condicionado (en general menos fuerte). Por ejemplo, un animal que ha aprendido que cierto timbre predice la llegada de comida, podría aprender también que hay una luz que predice el tono y entonces responder nada más a la luz. (También conocido como *condicionamiento de segundo orden*). (p. 276)
hindsight bias the tendency to believe, after learning an outcome, that one would have foreseen it. (Also known as the *I-knew-it-all-along phenomenon.*) (p. 38)	**distorsión retrospectiva** tendencia a creer, al enterarse de un resultado, que uno lo pudo haber previsto. (También conocido como el fenómeno de *yo ya lo sabía*). (p. 38)
hippocampus a neural center located in the limbic system; helps process for storage explicit (conscious) memories of facts and events. (pp. 106, 340)	**hipocampo** centro neuronal ubicado en el sistema límbico; ayuda a procesar recuerdos explícitos (conscientes) de hechos y eventos para almacenarlos de manera accesible. (pp. 106, 340)
histogram a bar graph depicting a frequency distribution. (p. 66)	**histograma** gráfica de barras que muestra una distribución de frecuencias. (p. 66)
homeostasis a tendency to maintain a balanced or constant internal state; the regulation of any aspect of body chemistry, such as blood glucose, around a particular level. (p. 403)	**homeostasis** tendencia a mantener un estado interno constante o equilibrado; la regulación de todos los aspectos de la química del organismo, tal como los niveles de glucosa, alrededor de un nivel particular. (p. 403)
hormones chemical messengers that are manufactured by the endocrine glands, travel through the bloodstream, and affect other tissues. (p. 95)	**hormonas** mensajeros químicos producidos por las glándulas endocrinas, que circulan por la sangre y tienen efecto en los tejidos del cuerpo. (p. 95)
hue the dimension of color that is determined by the wavelength of light; what we know as the color names *blue, green,* and so forth. (p. 177)	**tono** dimensión del color determinada por la longitud de la onda de luz; lo que conocemos como los nombres de los colores: *azul, verde*, etc. (p. 177)
human factors psychology a field of psychology allied with I/O	**psicología de factores humanos** división de la psicología relacionada con la

psychology that explores how people and machines interact and how machines and physical environments can be made safe and easy to use. (p. 24)	psicología I/O que explora la interacción entre las personas y las máquinas, y las maneras de hacer que las máquinas y los entornos físicos sean más seguros y fáciles de utilizar. (p. 24)
humanistic psychology a historically significant perspective that emphasized human growth potential. (p. 11)	**psicología humanista** perspectiva de importancia histórica que enfatiza el potencial de crecimiento de las personas. (p. 11)
humanistic theories theories that view personality with a focus on the potential for healthy personal growth. (p. 591)	**teorías humanistas** teorías que perciben a la personalidad con un enfoque sobre el potencial para un crecimiento personal saludable. (p. 591)
hypnagogic sensations bizarre experiences, such as jerking or a feeling of falling or floating weightlessly, while transitioning to sleep. (p. 233)	**sensaciones hipnagógicas** experiencias extrañas, como sacudirse o una sensación de caer o flotar de manera ligera, mientras uno transita hacia el sueño. (p. 233)
hypnosis a social interaction in which one person (the hypnotist) suggests to another (the subject) that certain perceptions, feelings, thoughts, or behaviors will spontaneously occur. (p. 225)	**hipnosis** interacción social en la cual una persona (el hipnotizador) le sugiere a otra persona (el sujeto) que ciertas percepciones, sentimientos, pensamientos o comportamientos se producirán espontáneamente. (p. 225)
hypothalamus [hi-po-THAL-uh-muss] a neural structure lying below *(hypo)* the thalamus; it directs several maintenance activities (eating, drinking, body temperature), helps govern the endocrine system via the pituitary gland, and is linked to emotion and reward. (p. 104)	**hipotálamo** estructura neuronal localizada debajo (*hipo*) del tálamo; regula actividades como comer, beber, y la temperatura del cuerpo; dirige varias actividades de mantenimiento (comer, beber, temperatura corporal); ayuda a dirigir el sistema endocrino a través de la glándula pituitaria, y está conectado a las emociones y las recompensas. (p. 104)
hypothesis a testable prediction, often implied by a theory. (p. 42)	**hipótesis** predicción comprobable, a menudo implicada por una teoría (p. 42)
I	
iconic memory a momentary sensory memory of visual stimuli; a picture-image memory lasting no more than a few tenths of a second. (p. 332)	**memoria icónica** recuerdo sensorial momentáneo de un estímulo visual; un recuerdo parecido a una fotografía que dura no más de algunas

	décimas de segundo. (p. 332)
id a reservoir of unconscious psychic energy that, according to Freud, strives to satisfy basic sexual and aggressive drives. The id operates on the *pleasure principle*, demanding immediate gratification. (p. 580)	**id** depósito de energía psíquica inconsciente que, según Freud, busca satisfacer los impulsos sexuales y agresivos esenciales. El id funciona de acuerdo al *principio del placer*, exigiendo satisfacción inmediata. (p. 580)
identical (monozygotic) twins develop from a single fertilized egg that splits in two, creating two genetically identical organisms. (p. 131)	**gemelos idénticos (monozigóticos)** se desarrollan de un solo óvulo fertilizado que se subdivide en dos para así crear dos organismos genéticamente idénticos. (p. 131)
identification the process by which, according to Freud, children incorporate their parents' values into their developing superegos. (p. 581)	**identificación** proceso en el que, según Freud, los niños incorporan los valores de sus padres en sus superegos en vías de desarrollo. (p. 581)
identity our sense of self; according to Erikson, the adolescent's task is to solidify a sense of self by testing and integrating various roles. (p. 539)	**identidad** sentido de autorreconocimiento; según Erikson, la tarea del adolescente consiste en solidificar su sentido de sí mismo probando e integrando una variedad de papeles. (p. 539)
illness anxiety disorder a disorder related to somatic symptom disorder in which a person interprets normal physical sensations as symptoms of a disease. (Formerly called *hypochondriasis*.) (p. 707)	**trastorno de ansiedad por enfermedad** trastorno relacionado con el trastorno de síntomas somáticos, donde una persona interpreta sensaciones físicas normales como síntomas de una enfermedad. (Anteriormente conocida como *hipocondriasis*). (p. 707)
illusory correlation perceiving a relationship where none exists, or perceiving a stronger-than-actual relationship. (p. 53)	**correlación ilusoria** percibir una relación donde no la hay, o percibir una relación más fuerte de la que sí existe. (p. 53)
implicit memory retention of learned skills or classically conditioned associations independent of conscious recollection. (Also called *nondeclarative memory*.) (p. 331)	**memoria implícita** retención de habilidades aprendidas o asociaciones condicionadas clásicas, sin tener consciencia del aprendizaje. (También se le dice *memoria no declarativa*). (p. 331)
imprinting	**impronta**

the process by which certain animals form strong attachments during early life. (p. 510)	proceso mediante el cual ciertos animales forman lazos fuertes desde el inicio de sus vidas. (p. 510)
inattentional blindness failing to see visible objects when our attention is directed elsewhere. (p. 160)	**ceguera por falta de atención** incapacidad para ver objetos visibles cuando nuestra atención se dirige a otra parte. (p. 160)
incentive a positive or negative environmental stimulus that motivates behavior. (p. 403)	**incentivo** estímulo positivo o negativo del entorno que motiva el comportamiento. (p. 403)
independent variable in an experiment, the factor that is manipulated; the variable whose effect is being studied. (p. 55)	**variable independiente** factor que se manipula en un experimento; la variable cuyo efecto es el objeto de estudio. (p. 55)
individualism giving priority to one's own goals over group goals and defining one's identity in terms of personal attributes rather than group identifications. (p. 616)	**individualismo** priorizar las metas personales sobre las metas del grupo, y definir la identidad propia a través de cualidades personales y no por la identificación del grupo. (p. 616)
industrial-organizational (I/O) psychology the application of psychological concepts and methods to optimizing human behavior in workplaces. (p. 24)	**psicología industrial y organizacional (I/O)** aplicación de conceptos y métodos psicológicos al comportamiento humano en el entorno laboral. (p. 24)
inferential statistics numerical data that allow one to generalize —to infer from sample data the probability of something being true of a population. (p. 70)	**estadística inferencial** datos numéricos que permiten generalizar — o inferir a partir de los datos de una muestra — la probabilidad de que algo sea verdadero dentro de una población. (p. 70)
informational social influence influence resulting from one's willingness to accept others' opinions about reality. (p. 778)	**influencia social informativa** influencia resultante de la disposición de una persona a aceptar las opiniones de otros acerca de la realidad. (p. 778)
informed consent giving potential participants enough information about a study to enable them to choose whether they wish to participate. (p. 62)	**consentimiento informado** dar a las personas información suficiente sobre un estudio para permitirles decidir si desean o no participar. (p. 62)
ingroup	**endogrupo**

“us”—people with whom we share a common identity. (p. 796)	“nosotros”; personas con quienes uno comparte una identidad común. (p. 796)
ingroup bias the tendency to favor our own group. (p. 796)	**estereotipo de grupo propio** tendencia a favorecer al grupo al que se pertenece. (p. 796)
inner ear the innermost part of the ear, containing the cochlea, semicircular canals, and vestibular sacs. (p. 199)	**oído interno** parte más interna del oído; contiene la cóclea, los canales semicirculares y los sacos vestibulares. (p. 199)
insecure attachment demonstrated by infants who display either a clinging, *anxious attachment* or an *avoidant attachment* that resists closeness. (p. 511)	**apego inseguro** comportamiento de infantes muestran un *apego ansioso* aferrado o un *apego evasivo* que evita la cercanía. (p. 511)
insight a sudden realization of a problem’s solution; contrasts with strategy-based solutions. (pp. 304, 370)	**agudeza** entendimiento repentino de cómo se resuelve un problema; contrasta con las soluciones basadas en estrategias. (pp. 304, 370)
insight therapies therapies that aim to improve psychological functioning by increasing a person’s awareness of underlying motives and defenses. (p. 725)	**tratamientos con agudeza** terapias que aspiran a mejorar el funcionamiento psicológico mediante el aumento en la conciencia de la persona de los motivos y las defensas subyacentes. (p. 725)
insomnia recurring problems in falling or staying asleep. (p. 244)	**insomnio** dificultades recurrentes para quedarse dormido o conciliar el sueño. (p. 244)
instinct a complex behavior that is rigidly patterned throughout a species and is unlearned. (p. 402)	**instinto** comportamiento complejo rígidamente arraigado a una especie y que no es aprendido. (p. 402)
instinctive drift the tendency of learned behavior to gradually revert to biologically predisposed patterns. (p. 303)	**deriva instintiva** tendencia de los aprendizajes aprendidos a revertirse gradualmente a patrones biológicos predispuestos. (p. 303)
intellectual disability a condition of limited mental ability, indicated by an intelligence test score of 70 or below and difficulty adapting to the	**discapacidad intelectual** estado de capacidad mental limitada, que se expresa a través de una puntuación de prueba de inteligencia de 70 o menos y de la

demands of life. (Formerly referred to as *mental retardation.*) (p. 644)	dificultad para adaptarse a las exigencias de la vida. (Anteriormente conocida como *retraso mental*). (p. 644)
intelligence quotient (IQ) defined originally as the ratio of mental age (*ma*) to chronological age (*ca*) multiplied by 100 (thus, $\text{IQ} = ma/ca \times 100$). On contemporary intelligence tests, the average performance for a given age is assigned a score of 100. (p. 634)	**coeficiente intelectual (CI)** cifra definida originalmente como la edad mental (*em*) dividida entre la edad cronológica (*ec*) y el resultado multiplicado por 100 (por lo tanto, $\text{CI} = em/ec \times 100$). En las pruebas actuales de inteligencia, al desempeño promedio en una prueba de inteligencia se le asigna un puntaje de 100.
intelligence test a method for assessing an individual’s mental aptitudes and comparing them with those of others, using numerical scores. (p. 632)	**prueba de inteligencia** método para evaluar las aptitudes mentales de los individuos y compararlas con las de otros a través de puntajes numéricos. (p. 632)
intelligence the ability to learn from experience, solve problems, and use knowledge to adapt to new situations. (p. 626)	**inteligencia** capacidad de aprender de las experiencias, de resolver problemas y de utilizar el conocimiento para adaptarse a situaciones nuevas. (p. 626)
intensity the amount of energy in a light wave or sound wave, which influences what we perceive as brightness or loudness. Intensity is determined by the wave’s amplitude (height). (p. 177)	**intensidad** cantidad de energía en una onda de luz o en una onda sonora que percibimos como brillo o volumen. La intensidad la determina la amplitud (altura) de la onda. (p. 177)
interaction the interplay that occurs when the effect of one factor (such as environment) depends on another factor (such as heredity). (p. 137)	**interacción** la situación que se produce cuando el efecto de un factor (por ejemplo, el entorno) depende de otro factor (por ejemplo, la herencia). (p. 137)
internal locus of control the perception that we control our own fate. (p. 309)	**foco de control interno** impresión de que controlamos nuestro propio destino. (p. 309)
interneurons neurons within the brain and spinal cord; they communicate internally and process information between the sensory inputs and motor outputs. (p. 93)	**interneuronas** neuronas ubicadas dentro del cerebro y la médula espinal. Se comunican internamente y procesan la información entre los estímulos sensoriales y las respuestas motoras. (p. 93)

interpretation in psychoanalysis, the analyst’s noting supposed dream meanings, resistances, and other significant behaviors and events in order to promote insight. (p. 723)	**interpretación** en psicoanálisis, las observaciones del analista con relación al significado de los sueños, las resistencias, y otras conductas y eventos significativos, a fin de promover la sagacidad. (p. 723)
intersex a condition present at birth due to unusual combinations of male and female chromosomes, hormones, and anatomy; possessing biological sexual characteristics of both sexes. (p. 547)	**intersexo** condición al momento del nacimiento en la que el recién nacido presenta características sexuales biológicas de ambos sexos. (p. 547)
intimacy in Erikson’s theory, the ability to form close, loving relationships; a primary developmental task in young adulthood. (p. 540)	**intimidad** según la teoría de Erikson, la capacidad de formar relaciones amorosas cercanas; una de las principales funciones de desarrollo en la adultez temprana. (p. 540)
intrinsic motivation a desire to perform a behavior effectively for its own sake. (p. 305)	**motivación intrínseca** deseo de realizar una conducta de manera adecuada simplemente por la mera satisfacción de hacerlo bien. (p. 305)
introspection the process of looking inward in an attempt to directly observe one’s own psychological processes. (p. 8)	**introspección** el proceso de mirar hacia adentro para tratar de observar los procesos psicológicos propios. (p. 8)
intuition an effortless, immediate, automatic feeling or thought, as contrasted with explicit, conscious reasoning. (p. 372)	**intuición** sentimiento o pensamiento automático e inmediato, que no precisa esfuerzo alguno, que se contrasta con el razonamiento explícito y consciente. (p. 372)
iris a ring of muscle tissue that forms the colored portion of the eye around the pupil and controls the size of the pupil opening. (p. 177)	**iris** tejido musculoso en forma de aro que forma la sección colorida de los ojos alrededor de la pupila y controla el tamaño de la apertura de la pupila. (p. 177)
J	
James-Lange theory the theory that our experience of emotion is our awareness of our physiological responses to an emotion-arousing stimulus: stimulus S	**teoría de James-Lange** teoría según la cual nuestra experiencia de la emoción es nuestro conocimiento de nuestras respuestas fisiológicas a estímulos que

arousal S emotion. (p. 433)	despiertan emociones: estímulo S respuesta S emoción. (p. 433)
just-world phenomenon the tendency for people to believe the world is just and that people therefore get what they deserve and deserve what they get. (p. 796)	**fenómeno del “mundo justo”** tendencia a creer que el mundo es justo y que por tanto, las personas obtienen lo que se merecen y se merecen lo que obtienen. (p. 796)
K	
kinesthesia [kin-ehs-THEE-zhuh] our movement sense—our system for sensing the position and movement of individual body arts. (p. 213)	**cinestesia** nuestro sentido del movimiento; nuestro sistema para sentir la posición y movimiento de partes individuales del cuerpo. (p. 213)
L	
language our spoken, written, or signed words and the ways we combine them to communicate meaning. (p. 381)	**lenguaje** palabras habladas, escritas o en señas y las maneras que se combinan para comunicar significado. (p. 381)
latent content according to Freud, the underlying meaning of a dream (as distinct from its manifest content). (p. 248)	**contenido latente** según Freud, significado subyacente de un sueño (a diferencia de su contenido manifiesto). (p. 248)
latent learning learning that occurs but is not apparent until there is an incentive to demonstrate it. (p. 304)	**aprendizaje latente** aprendizaje que no es aparente sino hasta que hay un incentivo para demostrarlo. (p. 304)
law of effect Thorndike’s principle that behaviors followed by favorable consequences become more likely, and that behaviors followed by unfavorable consequences become less likely. (p. 283)	**ley de efecto** principio propuesto por Thorndike en el que se propone que las conductas seguidas por consecuencias favorables se vuelven más comunes, mientras que las conductas seguidas por consecuencias desfavorables se repiten con menor frecuencia. (p. 283)
learned helplessness the hopelessness and passive resignation an animal or person learns when unable to avoid repeated aversive events. (p. 307)	**indefensión aprendida** desesperación y resignación pasiva que un animal o persona desarrollan cuando son incapaces de evitar eventos repetidos que generan aversión. (p. 307)

learning the process of acquiring through experience new and relatively enduring information or behaviors. (p. 270)	**aprendizaje** proceso de adquirir, mediante la experiencia información o conductas nuevas y relativamente permanentes. (p. 270)
lens the transparent structure behind the pupil that changes shape to help focus images on the retina. (p. 177)	**lente** estructura transparente ubicada detrás de la pupila que cambia de forma para ayudar a enfocar imágenes en la retina. (p. 177)
lesion [LEE-zhuhn] tissue destruction. A brain lesion is a naturally or experimentally caused destruction of brain tissue. (p. 98)	**lesión** destrucción de tejido. Las lesiones cerebrales generalmente son el resultado de destrucción del tejido cerebral. (p. 98)
limbic system neural system (including the *amygdala, hypothalamus*, and *hippocampus*) located below the cerebral hemispheres; associated with emotions and drives. (p. 104)	**sistema límbico** sistema de neuronas (incluye la *amígdala*, el *hipotálamo* y el *hipocampo*), ubicado debajo de los hemisferios cerebrales; se lo asocia con las emociones y los impulsos. (p. 104)
linguistic determinism the strong form of Whorf's hypothesis—that language controls the way we think and interpret the world around us. (p. 389)	**determinismo lingüístico** versión fuerte de la hipótesis de Whorf; que el lenguaje controla cómo pensamos e interpretamos el mundo que nos rodea. (p. 389)
linguistic influence the weaker form of "linguistic relativity"—the idea that language *affects* thought (thus our thinking and world view is "relative to" our cultural language). (p. 389)	**influencia lingüística** la versión débil de la "relatividad lingüística"; la idea de que el lenguaje *afecta* al pensamiento (y por tanto nuestro pensamiento y perspectiva del mundo es "relativo" a nuestro lenguaje cultural). (p. 389)
lobotomy a psychosurgical procedure once used to calm uncontrollably emotional or violent patients. The procedure cut the nerves connecting the frontal lobes to the emotion-controlling centers of the inner brain. (p. 758)	**lobotomía** procedimiento psicoquirúrgico que otrora se usó para calmar a pacientes emocionalmente incontrolables o violentos. En el procedimiento se cortaban los nervios entre los lóbulos frontales y los centros en el interior del cerebro que controlan las emociones. (p. 758)
long-term memory the relatively permanent and limitless storehouse of the memory system. Includes knowledge, skills, and experiences. (p. 329)	**memoria de largo plazo** el almacenamiento relativamente permanente e ilimitado del sistema de memoria. Incluye conocimientos, habilidades y experiencias.

	(p. 329)
long-term potentiation (LTP) an increase in a cell’s firing potential after brief, rapid stimulation; a neural basis for learning and memory. (p. 342)	**potenciación a largo plazo (PLP)** aumento en la eficacia de una célula para transmitir impulsos sinápticos. Se considera la base neuronal del aprendizaje y la memoria. (p. 342)
longitudinal study research that follows and retests the same people over time. (pp. 563, 640)	**estudio longitudinal** investigación en la que las mismas personas se estudian una y otra vez durante un lapso de tiempo prolongado. (pp. 563, 640)
LSD a powerful hallucinogenic drug; also known as acid *(lysergic acid diethylamide)*. (p. 262)	**LSD/ácido lisérgico** poderoso fármaco alucinógeno; también se conoce como ácido (dietilamida de ácido lisérgico). (p. 262)
M	
major depressive disorder a disorder in which a person experiences, in the absence of drugs or another medical condition, two or more weeks with five or more symptoms, at least one of which must be either (1) depressed mood or (2) loss of interest or pleasure. (p. 687)	**trastorno depresivo mayor** trastorno en el cual una persona —sin padecer alguna afección médica y sin usar drogas— pasa dos o más semanas con cinco o más síntomas, de los cuales al menos uno tiene que ser ya sea (1) un estado de ánimo deprimido o (2) la pérdida de interés o placer. (p. 687)
mania a hyperactive, wildly optimistic state in which dangerously poor judgment is common. (p. 687)	**manía** estado de ánimo marcado por un estado de hiperactividad y optimismo desenfrenado, caracterizado por la falta de juicio. (p. 687)
manifest content according to Freud, the symbolic, remembered story line of a dream (as distinct from its latent, or hidden, content). (p. 248)	**contenido manifiesto** según Freud, trama del sueño que se recuerda al despertarse (a diferencia del contenido latente o contenido oculto). (p. 248)
maturation biological growth processes that enable orderly changes in behavior, relatively uninfluenced by experience. (p. 494)	**maduración** procesos de crecimiento biológico que casi siempre conducen a cambios ordenados en el comportamiento y son independientes de la experiencia. (p. 494)
mean the arithmetic average of a distribution,	**promedio** media aritmética de una distribución que se

obtained by adding the scores and then dividing by the number of scores. (p. 67)	obtiene sumando las puntuaciones y luego dividiendo el total entre el número de puntuaciones. (p. 67)
median the middle score in a distribution; half the scores are above it and half are below it. (p. 67)	**media** puntuación central de una distribución; la mitad de las puntuaciones se encuentran por encima y la mitad se encuentran por debajo de la media. (p. 67)
medical model the concept that diseases, in this case psychological disorders, have physical causes that can be *diagnosed*, *treated*, and, in most cases, *cured*, often through treatment in a *hospital*. (p. 667)	**modelo médico** concepto que afirma que las enfermedades, en este caso los trastornos psicológicos, tienen causas físicas que se pueden *diagnosticar*, *tratar* y, en la mayoría de los casos, *curar*, generalmente por medio de tratamientos que se llevan a cabo en un *hospital*. (p. 667)
medulla [muh-DUL-uh] the base of the brainstem; controls heartbeat and breathing. (p. 102)	**médula** base del tronco encefálico; controla la frecuencia cardíaca y la respiración. (p. 102)
MEG (magnetoencephalography) a brain imaging technique that measures magnetic fields from the brain’s natural electrical activity. (p. 99)	**MEG (magnetoencefalografía)** técnica para tomar imágenes del cerebro que mide los campos magnéticos de la actividad eléctrica natural del cerebro. (p. 99)
memory consolidation the neural storage of a long-term memory. (p. 340)	**consolidación de la memoria** almacenaje neural de la memoria a largo plazo. (p. 340)
memory the persistence of learning over time through the encoding, storage, and retrieval of information. (p. 326)	**memoria** aprender de manera persistente a través del tiempo usando la codificación, el almacenaje y la recuperación de la información. (p. 326)
menarche [meh-NAR-key] the first menstrual period. (p. 547)	**menarquía** primer periodo menstrual. (p. 547)
menopause the time of natural cessation of menstruation; also refers to the biological changes a woman experiences as her ability to reproduce declines. (p. 558)	**menopausia** el momento del cese natural de la menstruación; también se refiere a los cambios biológicos que experimentan las mujeres cuando disminuye su capacidad reproductiva. (p. 558)

mental age a measure of intelligence test performance devised by Binet; the level of performance typically associated with children of a certain chronological age. Thus, a child who does as well as an average 8-year-old is said to have a mental age of 8. (p. 633)	**edad mental** medida de desempeño en la prueba de inteligencia diseñada por Binet. La edad cronológica del niño que corresponde característicamente a un nivel dado de desempeño. Por ende, se dice que un niño que se desempeña como una persona normal de 8 años, tiene una edad mental de 8 años. (p. 633)
mental set a tendency to approach a problem in one particular way, often a way that has been successful in the past. (p. 371)	**mentalidad** tendencia a abordar los problemas de una manera particular, con frecuencia, una manera que ha funcionado anteriormente. (p. 371)
mere exposure effect the phenomenon that repeated exposure to novel stimuli increases liking of them. (p. 808)	**efecto de la mera exposición** fenómeno que sostiene que la exposición repetida a estímulos novedosos aumenta la atracción a tales estímulos. (p. 808)
meta-analysis a procedure for statistically combining the results of many different research studies. (p. 743)	**meta-análisis** procedimiento para combinar estadísticamente los resultados de muchas investigaciones diferentes. (p. 743)
methamphetamine a powerfully addictive drug that stimulates the central nervous system, with accelerated body functions and associated energy and mood changes; over time, appears to reduce baseline dopamine levels. (p. 260)	**metanfetamina** fármaco poderosamente adictivo que estimula el sistema nervioso central con funciones corporales aceleradas y los cambios correspondientes de la energía y el estado de ánimo. Con el tiempo, parece reducir los niveles de referencia de dopamina. (p. 260)
middle ear the chamber between the eardrum and cochlea containing three tiny bones (hammer, anvil, and stirrup) that concentrate the vibrations of the eardrum on the cochlea’s oval window. (p. 199)	**oído medio** cámara ubicada entre el tímpano y la cóclea; contiene tres huesos pequeños (el martillo, el yunque y el estribo) que concentran las vibraciones del tímpano y de la ventana oval de la cóclea. (p. 199)
mindfulness meditation a reflective practice in which people attend to current experiences in a nonjudgmental and accepting manner. (p. 470)	**meditación a conciencia plena** práctica reflexiva en la que las personas atienden a las vivencias del momento de una manera tolerante y no condenatoria. (p. 470)
Minnesota Multiphasic Personality	**Inventario de Personalidad Polifacética de**

Inventory (MMPI) the most widely researched and clinically used of all personality tests. Originally developed to identify emotional disorders (still considered its most appropriate use), this test is now used for many other screening purposes. (p. 598)	**Minnesota (IPPM)** prueba de personalidad más ampliamente investigada y utilizada de todas las pruebas. Creada originalmente para identificar trastornos emocionales (y todavía se la utiliza con tal fin), esta prueba se utiliza en la actualidad para muchas actividades de preselección. (p. 598)
mirror neurons frontal lobe neurons that some scientists believe fire when we perform certain actions or observe another doing so. The brain's mirroring of another's action may enable imitation and empathy. (p. 313)	**neuronas espejo** neuronas del lóbulo frontal que, según algunos científicos, se disparan cuando llevamos a cabo ciertas acciones o cuando vemos que las hace alguien más. Esta forma del cerebro de reflejar las acciones de otros posiblemente habilite la imitación y la empatía. (p. 313)
mirror-image perceptions mutual views often held by conflicting people, as when each side sees itself as ethical and peaceful and views the other side as evil and aggressive. (p. 820)	**percepciones idénticas** opiniones mutuas que generalmente sostienen las personas que discrepan o experimentan conflictos entre sí, como cuando cada parte se ve a sí misma como ética y pacifica, y a la otra parte la ve como malvada y agresiva. (p. 820)
misinformation effect occurs when misleading information has distorted one's memory of an event. (p. 357)	**efecto de información errónea** recuerdo que se deforma al recibir información engañosa. (p. 357)
mnemonics [nih-MON-iks] memory aids, especially those techniques that use vivid imagery and organizational devices. (p. 333)	**nemotecnia** apoyos memorísticos, sobre todo técnicas que utilizan imágenes brillantes y dispositivos organizacionales. (p. 333)
mode the most frequently occurring score(s) in a distribution. (p. 67)	**moda** puntuación o puntuaciones que ocurren con mayor frecuencia en una distribución. (p. 67)
modeling the process of observing and imitating a specific behavior. (p. 312)	**modelar** proceso de observar e imitar un comportamiento en particular. (p. 312)
molecular behavior genetics the study of how the structure and function of genes interact with our environment to influence behavior. (p. 137)	**genética del comportamiento molecular** el estudio de cómo la estructura y la función de los genes interactúa con nuestro entorno para influir en nuestro comportamiento. (p. 137)

molecular genetics the subfield of biology that studies the molecular structure and function of genes. (p. 137)	**genética molecular** área de la biología que estudia la estructura molecular y la función de los genes. (p. 137)
monocular cue a depth cue, such as interposition or linear perspective, available to either eye alone. (p. 190)	**indicación monocular** señal de profundidad como la interposición y la perspectiva lineal, que se puede percibir con un ojo a la vez. (p. 190)
mood-congruent memory the tendency to recall experiences that are consistent with one’s current good or bad mood. (p. 346)	**memoria congruente con el estado de ánimo** tendencia a recordar experiencias que concuerdan con el buen o mal estado de ánimo que estamos viviendo. (p. 346)
morpheme in a language, the smallest unit that carries meaning; may be a word or a part of a word (such as a prefix). (p. 382)	**morfema** en un lenguaje, la unidad más pequeña que lleva significado; puede ser una palabra o parte de una palabra (por ejemplo, un prefijo). (p. 382)
motivation a need or desire that energizes and directs behavior. (p. 402)	**motivación** necesidad o deseo que promueve y dirige el comportamiento. (p. 402)
motor (efferent) neurons neurons that carry outgoing information from the brain and spinal cord to the muscles and glands. (p. 93)	**neurona motriz (eferente)** neurona que lleva la información desde el cerebro y la médula espinal hacia los músculos y las glándulas. (p. 93)
motor cortex an area at the rear of the frontal lobes that controls voluntary movements. (p. 110)	**corteza motora** parte de la corteza cerebral en la parte posterior de los lóbulos frontales. Controla los movimientos voluntarios. (p. 110)
MRI (magnetic resonance imaging) a technique that uses magnetic fields and radio waves to produce computer-generated images of soft tissue. MRI scans show brain anatomy. (p. 99)	**imagen de resonancia magnética (IRM)** técnica que emplea campos magnéticos y ondas de radio para producir imágenes computarizadas de tejidos blandos. Las imágenes de IRM nos permiten visualizar la anatomía del cerebro. (p. 99)
mutation a random error in gene replication that leads to a change. (p. 142)	**mutación** error aleatorio en la replicación de los genes que provoca a un cambio. (p. 142)

myelin [MY-uh-lin] **sheath** a fatty tissue layer segmentally encasing the axons of some neurons; enables vastly greater transmission speed as neural impulses hop from one node to the next. (p. 82)	**funda de mielina** tejido adiposo que cubre los axones de algunas neuronas; habilita velocidades de transmisión más alta para enviar impulsos neurales de un nodo al siguiente. (p. 82)

N

narcissism excessive self-love and self-absorption. (pp. 427, 615)	**narcisismo** amor propio y ensimismamiento excesivos. (pp. 427, 615)
narcolepsy a sleep disorder characterized by uncontrollable sleep attacks. The sufferer may lapse directly into REM sleep, often at inopportune times. (p. 245)	**narcolepsia** trastorno caracterizado por ataques incontrolables de sueño. Las personas con narcolepsia caen directamente en el sueño MOR incluso en momentos inoportunos. (p. 245)
natural selection the principle that inherited traits that better enable an organism to survive and reproduce in a particular environment will (in competition with other trait variations) most likely be passed on to succeeding generations. (pp. 14, 141)	**selección natural** principio según el cual los rasgos heredados que más ayudan a un organismo a sobrevivir en cierto entorno, serán (en competencia con otras variaciones) las que más probablemente se transmitan a las generaciones futuras. (pp. 14, 141)
naturalistic observation a descriptive technique of observing and recording behavior in naturally occurring situations without trying to manipulate or control the situation. (p. 45)	**observación naturalista** técnica descriptiva de observar y registrar la conducta en situaciones reales sin tratar de manipular ni controlar la situación. (p. 45)
nature–nurture issue the longstanding controversy over the relative contributions that genes and experience make to the development of psychological traits and behaviors. Today’s science sees traits and behaviors arising from the interaction of nature and nurture. (p. 14)	**debate de naturaleza–crianza** controversia de antaño acerca del aporte relativo que ejercen los genes y las vivencias en el desarrollo de los rasgos y comportamientos psicológicos. En la ciencia psicológica actual se opina que los rasgos y comportamientos tienen origen en la interrelación entre la naturaleza y la crianza. (p. 14)
near-death experience an altered state of consciousness reported after a close brush with death (such as cardiac arrest); often similar to drug-induced	**experiencia al borde de la muerte** estado de alteración de la consciencia experimentado por personas que tienen un encuentro cercano con la muerte (por

hallucinations. (p. 262)	ejemplo, cuando se sufre un paro cardíaco). A menudo es similar a las alucinaciones inducidas por los estupefacientes. (p. 262)
negative reinforcement increasing behaviors by stopping or reducing aversive stimuli. A negative reinforcer is any stimulus that, when *removed* after a response, strengthens the response. (*Note:* Negative reinforcement is not punishment.) (p. 285)	**reforzamiento negativo** aumento en la expresión de comportamientos mediante la interrupción o reducción de los estímulos negativos. Un reforzamiento negativo es todo aquello que, cuando se elimina después de una reacción, refuerza la reacción. (*Nota*: el reforzamiento negativo no significa castigo). (p. 285)
nerves bundled axons that form neural cables connecting the central nervous system with muscles, glands, and sense organs. (p. 92)	**nervios** conjuntos de axones neuronales que forman “cables” de nervios y conectan el sistema nervioso central con los músculos, las glándulas y los órganos sensoriales. (p. 92)
nervous system the body’s speedy, electrochemical communication network, consisting of all the nerve cells of the peripheral and central nervous systems. (p. 91)	**sistema nervioso** veloz red electroquímica de comunicación del cuerpo que consta de todas las células nerviosas del sistema nervioso central y periférico. (p. 91)
neurocognitive disorders (NCDs) acquired (not lifelong) disorders marked by cognitive deficits; often related to Alzheimer’s disease, brain injury or disease, or substance abuse. In older adults, neurocognitive disorders were formerly called *dementia*. (p. 563)	**trastornos neurocognitivos (TNC)** trastornos adquiridos (no de por vida) marcados por déficits cognitivos; con frecuencia se les relaciona con la enfermedad de Alzheimer, lesiones o enfermedades cerebrales o abuso de sustancias. Anteriormente se conocía a los trastornos neurocognitivos en adultos mayores como *demencia*. (p. 563)
neurogenesis the formation of new neurons. (p. 117)	**neurogénesis** formación de neuronas nuevas. (p. 117)
neuron a nerve cell; the basic building block of the nervous system. (p. 81)	**neurona** célula nerviosa; componente básico del sistema nervioso. (p. 81)
neurotransmitters chemical messengers that cross the synaptic gaps between neurons. When released by the sending neuron, neurotransmitters travel across the synapse and bind to receptor sites on the receiving neuron, thereby influencing	**neurotransmisores** mensajeros químicos que cruzan las sinapsis entre neuronas. Al ser liberados por la neurona, los neurotransmisores cruzan la sinapsis y se adhieren al sitio receptor de la neurona que los recibe y con ello influyen en

whether that neuron will generate a neural impulse. (p. 85)	si esa neurona generará un impulso neural. (p. 85)
neutral stimulus (NS) in classical conditioning, a stimulus that elicits no response before conditioning. (p. 273)	**estímulos neutrales (EN)** según el condicionamiento clásico, un estímulo que no produce respuesta antes del condicionamiento. (p. 273)
nicotine a stimulating and highly addictive psychoactive drug in tobacco. (p. 258)	**nicotina** fármaco estimulante, altamente adictivo y psicoactivo que se halla en el tabaco. (p. 258)
night terrors a sleep disorder characterized by high arousal and an appearance of being terrified; unlike nightmares, night terrors occur during NREM-3 sleep, within two or three hours of falling asleep, and are seldom remembered. (p. 246)	**terror nocturno** trastorno del sueño caracterizado por agitación y la apariencia de estar asustado; a diferencia de las pesadillas, los terrores nocturnos ocurren durante el sueño NMOR-3, dentro de dos o tres horas de quedarse dormido y rara vez son recordados. (p. 246)
normal curve (*normal distribution*) a symmetrical, bell-shaped curve that describes the distribution of many types of data; most scores fall near the mean (about 68 percent fall within one standard deviation of it) and fewer and fewer near the extremes. (pp. 68, 635)	**curva normal** (*distribución normal*) curva asimétrica en forma de campana que describe la distribución de muchos tipos de datos; la mayoría de los puntajes caen cerca de la media (cerca del 68 por ciento caen dentro de una desviación estándar de uno de la media) y hay cada vez menos cerca de los extremos. (pp. 68, 635)
normative social influence influence resulting from a person's desire to gain approval or avoid disapproval. (p. 777)	**influencia social normativa** influencia resultante del deseo de una persona de obtener la aprobación o evitar la desaprobación de los demás. (p. 777)
norms understood rules for accepted and expected behavior. Norms prescribe "proper" behavior. (p. 775)	**normas** reglas sobre el comportamiento aceptado y esperado. Las normas describen el comportamiento "apropiado". (p. 775)
NREM sleep non-rapid eye movement sleep; encompasses all sleep stages except for REM sleep. (p. 233)	**sueño NMOR** sueño sin movimiento ocular rápido; incluye todas las fases del sueño excepto el sueño MOR. (p. 233)
O	

obesity defined as a body mass index (BMI) measurement of 30 or higher. (Overweight individuals have a BMI of 25 or higher.) (p. 414)	**obesidad** se define como una medida de índice de masa corporal, (IMC) de 30 o más. (Los individuos con soprepeso tienen medidas de 25 o más). (p. 414)
object permanence the awareness that things continue to exist even when not perceived. (p. 499)	**permanencia de los objetos** reconocimiento de que las cosas siguen existiendo aunque no las veamos. (p. 499)
observational learning learning by observing others. (Also called *social learning*.) (p. 312)	**aprendizaje observacional** aprender observando a los demás. (También conocido como *aprendizaje social*.) (p. 312)
obsessive-compulsive disorder (OCD) a disorder characterized by unwanted repetitive thoughts (obsessions), actions (compulsions), or both. (p. 679)	**trastorno obsesivo-compulsivo (TOC)** trastorno que se caracteriza por pensamientos (obsesiones) y/o acciones (compulsiones) repetitivos y no deseados o ambos. (p. 679)
occipital [ahk-SIP-uh-tuhl] **lobes** the portion of the cerebral cortex lying at the back of the head; includes areas that receive information from the visual fields. (p. 110)	**lóbulos occipitales** sección de la corteza cerebral ubicada en la parte posterior de la cabeza; incluye las áreas que reciben información de los campos visuales. (p. 110)
Oedipus [ED-uh-puss] **complex** according to Freud, a boy's sexual desires toward his mother and feelings of jealousy and hatred for the rival father. (p. 580)	**complejo de Edipo** según Freud, los deseos sexuales de un niño hacia su madre y sentimientos de celos y odio hacia el padre rival. (p. 580)
olfaction the sense of smell. (p. 211)	**olfato** sentido del olor. (p. 211)
one-word stage the stage in speech development, from about age 1 to 2, during which a child speaks mostly in single words. (p. 384)	**etapa holofrástica** etapa en el desarrollo del habla, entre el primer y segundo año en la que el niño se expresa principalmente con palabras aisladas. (p. 384)
operant behavior behavior that operates on the environment, producing consequences. (p. 271)	**comportamiento operante** comportamiento que opera en el entorno, produciendo consecuencias. (p. 271)
operant chamber in operant conditioning research, a chamber (also known as a *Skinner box*) containing a	**cámara operante** Caja (también conocida como *cámara de Skinner*) que contiene una barra o tecla que

bar or key that an animal can manipulate to obtain a food or water reinforcer; attached devices record the animal’s rate of bar pressing or key pecking. (p. 284)	un animal puede manipular para obtener un reforzamiento de comida o agua; con una serie de dispositivos conectados se graba la cantidad de veces que el animal presiona la barra. (p. 284)
operant conditioning a type of learning in which a behavior becomes more likely to recur if followed by a reinforcer or less likely to recur if followed by a punisher. (p. 283)	**condicionamiento operante** aprendizaje en el que el comportamiento se torna más probable si es seguido por un reforzamiento o se atenúa si es seguido por un castigo. (p. 283)
operational definition a carefully worded statement of the exact procedures (operations) used in a research study. For example, *human intelligence* may be operationally defined as what an intelligence test measures. (p. 42)	**definición operacional** declaración redactada con gran cuidado en la que se detallan los procedimientos (operaciones) exactos que se usan en un estudio de investigación. Por ejemplo, la *inteligencia humana* puede ser operacionalmente definida como lo que se mide en una prueba de inteligencia. (p. 42)
opiates opium and its derivatives, such as morphine and heroin; depress neural activity, temporarily lessening pain and anxiety. (p. 257)	**opioides** el opio y sus derivados, tales como la morfina y la heroína; deprimen la actividad neuronal y alivian temporalmente el dolor y la ansiedad. (p. 257)
opponent-process theory the theory that opposing retinal processes (red-green, blue-yellow, white-black) enable color vision. For example, some cells are stimulated by green and inhibited by red; others are stimulated by red and inhibited by green. (p. 182)	**teoría de proceso de oponentes** Teoría que manifiesta que los procesos opuestos de la retina (rojo-verde, amarillo-azul, blanco-negro) posibilitan la visualización de los colores. Por ejemplo, algunas células se estimulan con el verde y se inhiben con el rojo; otras se estimulan con el rojo y se inhiben con el verde. (p. 182)
optic nerve the nerve that carries neural impulses from the eye to the brain. (p. 178)	**nervio óptico** nervio que transporta los impulsos neuronales del ojo al cerebro. (p. 178)
ostracism deliberate social exclusion of individuals or groups. (p. 425)	**ostracismo** exclusión social deliberada de individuos o grupos. (p. 425)
other-race effect the tendency to recall faces of one’s own race more accurately than faces of other	**efecto de otras razas** tendencia a recordar caras de la raza de uno mismo con mayor precisión que las caras de

races. Also called the *cross-race effect* and the *own-race bias*. (p. 797)	otras razas. También se conoce como *efecto de raza cruzada* o *sesgo de rasa propia*. (p. 797)
outgroup “them”—those perceived as different or apart from our ingroup. (p. 796)	**grupo ajeno** “ellos”, o, las personas a las que percibimos como distintas o separadas, que no forman parte de nuestro grupo. (p. 796)
overconfidence the tendency to be more confident than correct—to overestimate the accuracy of our beliefs and judgments. (p. 375)	**exceso de confianza** tendencia a ser más confiado que acertado, o sea, a sobreestimar las creencias y las opiniones propias. (p. 375)
P	
panic disorder an anxiety disorder marked by unpredictable, minuteslong episodes of intense dread in which a person may experience terror and accompanying chest pain, choking, or other frightening sensations; often followed by worry over a possible next attack. (p. 678)	**trastorno de pánico** trastorno de ansiedad marcado por el inicio repentino y recurrente de episodios impredecibles de aprehensión intensa o terror que pueden durar varios minutos, en los cuales la persona puede sentir dolor de pecho, sofocamiento, y otras sensaciones atemorizantes; a menudo la preocupación es por la posibilidad de un posible nuevo ataque. (p. 678)
parallel processing processing many aspects of a problem simultaneously; the brain’s natural mode of information processing for many functions. (pp. 126, 183, 329)	**procesamiento en paralelo** procesamiento simultáneo de muchos aspectos de un problema o escena; es la forma natural del cerebro de procesar muchas funciones. (pp. 126, 183, 329)
parapsychology the study of paranormal phenomena, including ESP and psychokinesis. (p. 172)	**parapsicología** el estudio de fenómenos paranormales, entre ellos percepción extrasensorial y telequinesis. (p. 172)
parasympathetic nervous system the division of the autonomic nervous system that calms the body, conserving its energy. (p. 93)	**sistema nervioso autonómico parasimpático** subdivisión del sistema nervioso autonómico que calma el cuerpo y conserva su energía. (p. 93)
parietal [puh-RYE-uh-tuhl] **lobes** the portion of the cerebral cortex lying at the top of the head and toward the rear; receives sensory input for touch and body position.	**lóbulos parietales** región de la corteza cerebral en la parte superior y hacia la parte posterior de la cabeza; recibe entradas sensoriales del tacto

(p. 109)	y la posición del cuerpo. (p. 109)
partial (intermittent) reinforcement schedule reinforcing a response only part of the time; results in slower acquisition of a response but much greater resistance to extinction than does continuous reinforcement. (p. 287)	**calendario de reforzamiento parcial (intermitente)** reforzamiento de una respuesta tan solo una parte del tiempo; tiene como resultado la adquisición más lenta de una respuesta pero mucho más resistente a la extinción que el reforzamiento continuo. (p. 287)
passionate love an aroused state of intense positive absorption in another, usually present at the beginning of a romantic relationship. (p. 812)	**amor apasionado** estado excitado de intensa y positiva absorción en otro ser. Por lo general se observa al comienzo de una relación de amor romántica. (p. 812)
perception the process of organizing and interpreting sensory information, enabling us to recognize meaningful objects and events. (p. 158)	**percepción** proceso mediante el cual el cerebro organiza e interpreta la información sensorial transformándola en objetos y sucesos que tienen sentido. (p. 158)
perceptual adaptation the ability to adjust to changed sensory input, including an artificially displaced or even inverted visual field. (p. 195)	**adaptación perceptiva** capacidad de ajustarnos a un estímulo sensorial cambiado, como por ejemplo un campo visual artificialmente desplazado o incluso invertido. (p. 195)
perceptual constancy perceiving objects as unchanging (having consistent color, brightness, shape, and size) even as illumination and retinal images change. (p. 191)	**constancia perceptiva** tendencia a percibir objetos como si fueran constantes e inalterables (como si mantuvieran el color, el brillo, la forma y el tamaño), a pesar de los cambios que se produzcan en la iluminación y en las imágenes que llegan a la retina. (p. 191)
perceptual set a mental predisposition to perceive one thing and not another. (p. 169)	**predisposición perceptiva** predisposición mental para percibir una cosa y no otra. (p. 169)
peripheral nervous system (PNS) the sensory and motor neurons that connect the central nervous system (CNS) to the rest of the body. (p. 92)	**sistema nervioso periférico (SNP)** neuronas sensoriales y motrices que conectan el sistema nervioso central con el resto del organismo. (p. 92)
peripheral route persuasion	**ruta de persuasión periférica**

occurs when people are influenced by incidental cues, such as a speaker's attractiveness. (p. 771)	se produce cuando las personas se ven influenciadas por señales triviales, como el atractivo del orador. (p. 771)
personal control our sense of controlling our environment rather than feeling helpless. (p. 306)	**control personal** nuestro sentido de controlar el entorno en lugar de sentirnos impotentes. (p. 306)
personality an individual's characteristic pattern of thinking, feeling, and acting. (p. 578)	**personalidad** forma característica de pensar, sentir y actuar de una persona. (p. 578)
personality disorders inflexible and enduring behavior patterns that impair social functioning. (p. 710)	**trastornos de la personalidad** patrón de comportamientos inflexibles y duraderos que se interponen ante el desempeño social. (p. 710)
personality inventory a questionnaire (often with *true-false* or *agree-disagree* items) on which people respond to items designed to gauge a wide range of feelings and behaviors; used to assess selected personality traits. (p. 598)	**inventario de personalidad** cuestionario (a menudo de preguntas de *falso o verdadero* o de *desacuerdo/acuerdo*) en el que las personas responden a consultas diseñadas para medir una amplia gama de sentimientos y conductas; se usa para evaluar ciertos rasgos de la personalidad. (p. 598)
personality psychology the study of individuals' characteristic patterns of thinking, feeling, and acting. (p. 24)	**psicología de la personalidad** el estudio de los patrones característicos de pensar, sentir y actuar de las persona. (p. 24)
PET (positron emission tomography) scan a visual display of brain activity that detects where a radioactive form of glucose goes while the brain performs a given task. (p. 99)	**TEP (tomografía por emisión de positrones)** muestra visual de la actividad cerebral que detecta hacia dónde se dirige un tipo de glucosa radiactiva en el momento en que el cerebro realiza una función particular. (p. 99)
phi phenomenon an illusion of movement created when two or more adjacent lights blink on and off in quick succession. (p. 190)	**fenómeno phi** ilusión de movimiento creada por dos o más luces adyacentes que parpadean en sucesión rápida. (p. 190)
phobia an anxiety disorder marked by a persistent, irrational fear and avoidance of a specific	**fobia** trastorno de ansiedad marcado por un temor persistente e irracional, y la evasión de un

object, activity, or situation. (p. 679)	objeto, actividad o situación específicos. (p. 679)
phoneme in a language, the smallest distinctive sound unit. (p. 381)	**fonema** en un lenguaje, la unidad distintiva de sonido más pequeña. (p. 381)
physiological need a basic bodily requirement. (p. 403)	**necesidad fisiológica** exigencia básica del cuerpo. (p. 403)
pitch a tone’s experienced highness or lowness; depends on frequency. (p. 198)	**tono** propiedad de los sonidos que los caracteriza como agudos o graves; depende de la frecuencia. (p. 198)
pituitary gland the endocrine system’s most influential gland. Under the influence of the hypothalamus, the pituitary regulates growth and controls other endocrine glands. (p. 96)	**glándula pituitaria** la glándula más influyente del sistema endocrino. Bajo la influencia del hipotálamo, la glándula pituitaria regula el crecimiento y controla las demás glándulas endocrinas. (p. 96)
place theory in hearing, the theory that links the pitch we hear with the place where the cochlea’s membrane is stimulated. (p. 202)	**teoría del lugar** en la audición, la teoría que relaciona el tono que escuchamos con el sitio donde se estimula la membrana de la cóclea. (p. 202)
placebo [pluh-SEE-bo; Latin for “I shall please”] **effect** experimental results caused by expectations alone; any effect on behavior caused by the administration of an inert substance or condition, which the recipient assumes is an active agent. (p. 55)	**efecto placebo** resultados producidos únicamente por las expectativas; cualquier efecto sobre el comportamiento causado por el suministro de una sustancia o condición inerte, que el receptor supone que es un agente activo. (p. 55)
plasticity the brain’s ability to change, especially during childhood, by reorganizing after damage or by building new pathways based on experience. (p. 116)	**plasticidad** capacidad del cerebro de modificarse, sobre todo durante la niñez, reordenándose después de un daño cerebral o formando nuevas trayectorias basadas en la experiencia. (p. 116)
polygraph a machine used in attempts to detect lies that measures several of the physiological responses (such as perspiration, heart rate, and breathing changes) accompanying	**polígrafo** máquina, utilizada comúnmente con la intención de detectar mentiras, que mide ciertas reacciones corporales (como los cambios en la transpiración, el ritmo

emotion. (p. 439)	cardíaco y la respiración) que acompañan a las emociones. (p. 439)
population all those in a group being studied, from which samples may be drawn. (*Note:* Except for national studies, this does not refer to a country’s whole population.) (p. 47)	**población** todos aquellos que constituyen el grupo que se está estudiando, a partir del cual se pueden tomar muestras. (*Nota*: salvo en estudios de alcance nacional, no se refiere a la totalidad de la población de un país). (p. 47)
positive psychology the scientific study of human flourishing, with the goals of discovering and promoting strengths and virtues that help individuals and communities to thrive. (pp. 16, 473)	**psicología positiva** estudio científico del funcionamiento humano, que tiene las metas de descubrir y promover las fortalezas y las virtudes que ayudan a los individuos y a las comunidades a prosperar. (pp. 16, 473)
positive reinforcement increasing behaviors by presenting positive reinforcers. A positive reinforcer is any stimulus that, when *presented* after a response, strengthens the response. (p. 285)	**reforzamiento positivo** aumento en la expresión de comportamientos mediante la presentación de estímulos positivos, por ejemplo, un alimento. Un reforzamiento positivo es cualquier cosa que, presentada después de una respuesta, refuerza esa respuesta. (p. 285)
posthypnotic suggestion a suggestion, made during a hypnosis session, to be carried out after the subject is no longer hypnotized; used by some clinicians to help control undesired symptoms and behaviors. (p. 226)	**sugerencia poshipnótica** sugerencia que se hace durante una sesión de hipnotismo, que el sujeto debe realizar cuando ya no está hipnotizado; la usan algunos practicantes para ayudar a controlar síntomas y conductas no deseadas. (p. 226)
posttraumatic growth positive psychological changes as a result of struggling with extremely challenging circumstances and life crises. (p. 760)	**crecimiento postraumático** cambios psicológicos positivos como resultado de la lucha contra circunstancias extremadamente difíciles y crisis de la vida. (p. 760)
posttraumatic stress disorder (PTSD) a disorder characterized by haunting memories, nightmares, hypervigilance, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia that lingers for four weeks or more after a traumatic experience. (p. 680)	**trastorno por estrés postraumático (TEPT)** trastorno de ansiedad caracterizado por recuerdos inquietantes, pesadillas, aislamiento social, ansiedad asustadiza, y/o insomnio que perdura por cuatro semanas o más después de una experiencia traumática. (p. 680)

predictive validity the success with which a test predicts the behavior it is designed to predict; it is assessed by computing the correlation between test scores and the criterion behavior. (Also called *criterion-related validity*.) (p. 637)	**validez predictiva** nivel de éxito con el que una prueba predice el comportamiento para el que ha sido diseñada para predecir. Se evalúa mediante la medición de la correlación de los resultados de las pruebas y el comportamiento de criterio. (También se conoce como *validez relacionada con el criterio*). (p. 637)
prejudice an unjustifiable (and usually negative) attitude toward a group and its members. Prejudice generally involves stereotyped beliefs, negative feelings, and a predisposition to discriminatory action. (p. 792)	**prejuicio** actitud injustificable y normalmente negativa hacia un grupo y sus integrantes. Los prejuicios generalmente implican creencias estereotipadas, sentimientos negativos y una predisposición a la acción discriminatoria. (p. 792)
preoperational stage in Piaget's theory, the stage (from about 2 to 6 or 7 years of age) during which a child learns to use language but does not yet comprehend the mental operations of concrete logic. (p. 500)	**etapa preoperacional** en la teoría de Piaget, la etapa (desde alrededor de los 2 hasta los 6 o 7 años de edad) durante la que el niño aprende a utilizar el lenguaje; pero todavía no comprende las operaciones mentales de la lógica concreta. (p. 500)
preparedness a biological predisposition to learn associations, such as between taste and nausea, that have survival value. (p. 300)	**estado de preparación** predisposición biológica a aprender asociaciones, por ejemplo entre cierto sabor y la sensación de náusea, que tienen valor para la supervivencia. (p. 300)
primary reinforcer an innately reinforcing stimulus, such as one that satisfies a biological need. (p. 286)	**reforzador primario** suceso que es inherentemente reforzador y a menudo satisface una necesidad biológica. (p. 286)
primary sex characteristics the body structures (ovaries, testes, and external genitalia) that make sexual reproduction possible. (p. 546)	**características primarias del sexo** estructuras del organismo (ovarios, testículos y aparatos genitales externos) que posibilitan la reproducción sexual. (p. 546)
priming the activation, often unconsciously, of certain associations, thus predisposing one's perception, memory, or response. (pp. 165, 345)	**preparación** activación de asociaciones en nuestra memoria, a menudo de manera inconsciente, que nos dispone a percibir o recordar objetos o sucesos de una manera determinada. (pp. 165, 345)

proactive interference the forward-acting disruptive effect of older learning on the recall of *new* information. (p. 354)	**interferencia proactiva** efecto interruptor del aprendizaje anterior sobre la manera de recordar información *nueva*. (p. 354)
problem-focused coping attempting to alleviate stress directly—by changing the stressor or the way we interact with that stressor. (p. 306)	**superación con enfoque en los problemas** intento de sobrellevar el estrés de manera directa cambiando ya sea lo que produce la tensión o la forma en que nos relacionamos con dicho factor de estrés. (p. 306)
projective test a personality test, such as the Rorschach, that provides ambiguous images designed to trigger projection of one's inner dynamics. (p. 584)	**prueba de proyección** tipo de prueba de la personalidad, como la prueba de Rorschach, que muestra imágenes ambiguas a los sujetos para provocar una proyección de sus dinámicas internas. (p. 584)
prosocial behavior positive, constructive, helpful behavior. The opposite of antisocial behavior. (p. 315)	**comportamiento prosocial** comportamiento positivo, constructivo, útil. Lo contrario del comportamiento antisocial. (p. 315)
prototype a mental image or best example of a category. Matching new items to a prototype provides a quick and easy method for sorting items into categories (as when comparing feathered creatures to a prototypical bird, such as a robin). (p. 365)	**prototipo** imagen mental o mejor ejemplo de una categoría. Al cotejar artículos nuevos con un prototipo se trabaja con un método rápido y sencillo para clasificar artículos en categorías (tal como cuando se comparan animales de plumas con un ave prototípico, como un petirrojo). (p. 365)
psychiatry a branch of medicine dealing with psychological disorders; practiced by physicians who are licensed to provide medical (for example, drug) treatments as well as psychological therapy. (p. 25)	**psiquiatría** rama de la medicina que se ocupa de los trastornos psicológicos; es ejercida por médicos que tienen licencia para ofrecer tratamientos (con medicamentos, por ejemplo), además de terapia psicológica. (p. 25)
psychoactive drug a chemical substance that alters perceptions and moods. (p. 253)	**fármaco psicoactivo** sustancia química que altera las percepciones y el estado de ánimo. (p. 253)
psychoanalysis (1) Freud's theory of personality that	**psicoanálisis** (1) teoría de Freud sobre la personalidad que

attributes thoughts and actions to unconscious motives and conflicts. (2) Sigmund Freud's therapeutic technique used in treating psychological disorders. Freud believed the patient's free associations, resistances, dreams, and transferences—and the therapist's interpretations of them—released previously repressed feelings, allowing the patient to gain self-insight. (pp. 579, 723)	atribuye los pensamientos y las acciones a motivos y conflictos inconscientes. (2) El método terapéutico de Freud usado para el tratamiento de trastornos psicológicos. Freud creía que las asociaciones libres, las resistencias, los sueños y las transferencias del paciente (así como la interpretación de ellas por parte del analista) liberaban sentimientos antes reprimidos, permitiendo que el paciente adquiriera agudeza introspectiva. (pp. 579, 723)
psychodynamic psychology a branch of psychology that studies how unconscious drives and conflicts influence behavior and uses that information to treat people with psychological disorders. (p. 18)	**psicología psicodinámica** rama de la psicología que estudia como los conflictos e impulsos inconscientes influyen en el comportamiento y que usa esa información para tratar a personas con trastornos psicológicos. (p. 18)
psychodynamic theories theories that view personality with a focus on the unconscious and the importance of childhood experiences. (p. 578)	**teorías psicodinámicas** visión de la personalidad con una concentración en el subconsciente y en la importancia de las vivencias en la niñez. (p. 578)
psychodynamic therapy therapy deriving from the psychoanalytic tradition; views individuals as responding to unconscious forces and childhood experiences, and seeks to enhance self-insight. (p. 724)	**terapia psicodinámica** enfoque terapéutico que se deriva de la tradición psicoanalítica; se observa a los individuos como si respondieran a fuerzas inconscientes y experiencias de la niñez, y se busca agudizar la introspección. (p. 724)
psychological disorder a syndrome marked by a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior. (p. 666)	**trastorno psicológico** síndrome caracterizado por la alteración clínicamente significativa de los pensamientos, los sentimientos y los comportamientos de una persona. (p. 666)
psychology the science of behavior and mental processes. (p. 13)	**psicología** estudio científico de los procesos psicológicos y mentales. (p. 13)
psychometrics the scientific study of the measurement of human abilities, attitudes, and traits. (p. 24)	**psicometría** estudio científico de medición de las habilidades, actitudes y rasgos humanos. (p. 24)
psychoneuroimmunology	**psiconeuroimunología**

the study of how psychological, neural, and endocrine processes together affect the immune system and resulting health. (p. 456)	estudio de cómo los procesos psicológicos, neuronales y endocrinos se combinan en nuestro organismo para influenciar el sistema inmunológico y la salud en general. (p. 456)
psychopharmacology the study of the effects of drugs on mind and behavior. (p. 753)	**psicofarmacología** estudio de los efectos de los medicamentos sobre la mente y el comportamiento. (p. 753)
psychophysics the study of relationships between the physical characteristics of stimuli, such as their intensity, and our psychological experience of them. (p. 162)	**psicofísica** el estudio de las relaciones entre las características físicas de los estímulos, por ejemplo su intensidad, y nuestra experiencia psicológica de esos estímulos. (p. 162)
psychosexual stages the childhood stages of development (oral, anal, phallic, latency, genital) during which, according to Freud, the id's pleasure-seeking energies focus on distinct erogenous zones. (p. 580)	**etapas psicosexuales** etapas del desarrollo infantil (oral, anal, fálica, latente, genital), durante las cuales, según Freud, las energías del id que buscan el placer se enfocan en zonas erógenas específicas. (p. 580)
psychosurgery surgery that removes or destroys brain tissue in an effort to change behavior. (p. 758)	**psicocirugía** cirugía que extrae o destruye tejido cerebral para cambiar el comportamiento. (p. 758)
psychotherapy treatment involving psychological techniques; consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth. (p. 722)	**psicoterapia** tratamiento que incluye técnicas psicológicas; consiste en interacciones entre un terapeuta cualificado y una persona que desea superar dificultades psicológicas o lograr un crecimiento personal. (p. 722)
psychotic disorders a group of disorders marked by irrational ideas, distorted perceptions, and a loss of contact with reality. (p. 699)	**trastornos psicóticos** conjunto de trastornos caracterizados por ideas irracionales, percepciones distorsionadas y pérdida de contacto con la realidad. (p. 699)
puberty the period of sexual maturation, during which a person becomes capable of reproducing. (p. 533)	**pubertad** período de maduración sexual durante el cual la persona adquiere la capacidad de reproducirse. (p. 533)
punishment an event that tends to *decrease* the behavior that it follows. (p. 289)	**castigo** evento que *disminuye* el comportamiento que le precede. (p. 289)

pupil the adjustable opening in the center of the eye through which light enters. (p. 177)	**pupila** la apertura ajustable del centro del ojo que permite el acceso de la luz. (p. 177)
R	
random assignment assigning participants to experimental and control groups by chance, thus minimizing preexisting differences between the different groups. (p. 54)	**asignación aleatoria** asignación de participantes al grupo experimental o al de control. Se realiza al azar para minimizar las diferencias preexistentes que pudiese haber entre los grupos asignados. (p. 54)
random sample a sample that fairly represents a population because each member has an equal chance of inclusion. (p. 47)	**muestra aleatoria** muestra que representa justamente la población, gracias a que cada elemento de la población tiene igual oportunidad de ser seleccionado. (p. 47)
range the difference between the highest and lowest scores in a distribution. (p. 68)	**rango** diferencia entre las puntuaciones más alta y más baja en una distribución. (p. 68)
rational-emotive behavior therapy (REBT) a confrontational cognitive therapy, developed by Albert Ellis, that vigorously challenges people’s illogical, self-defeating attitudes and assumptions. (p. 733)	**terapia racional emotiva conductual (TREC)** terapia cognitiva de confrontación desarrollada por Albert Ellis, que cuestiona vigorosamente las actitudes y suposiciones ilógicas y derrotistas de las personas. (p. 733)
recall a measure of memory in which the person must retrieve information learned earlier, as on a fill-in-the-blank test. (p. 327)	**recordación** memoria que se demuestra recuperando información aprendida anteriormente, tal como en las pruebas que consisten en rellenar espacios en blanco. (p. 327)
reciprocal determinism the interacting influences of behavior, internal cognition, and environment. (p. 606)	**determinismo reciproco** la interacción de las influencias del comportamiento, cognición intrna y el entorno. (p. 606)
reciprocity norm an expectation that people will help, not hurt, those who have helped them. (p. 818)	**norma de reciprocidad** expectativa de que las personas ayudarán, y no harán daño, a aquellos que las han ayudado. (p. 818)

recognition a measure of memory in which the person identifies items previously learned, as on a multiple-choice test. (p. 327)	**reconocimiento** memoria que se demuestra identificando cosas que se aprendieron anteriormente, tal como en las pruebas de opción múltiple. (p. 327)
reconsolidation a process in which previously stored memories, when retrieved, are potentially altered before being stored again. (p. 356)	**reconsolidación** proceso en el que los recuerdos almacenados, al ser recuperados, son potencialmente alterados antes de ser almacenados nuevamente. (p. 356)
reflex a simple, automatic response to a sensory stimulus, such as the knee-jerk response. (p. 94)	**reflejo** respuesta simple y automática a un estímulo sensorial, por ejemplo el reflejo rotular (mover la pierna para evitar un peligro repentino). (p. 94)
refractory period (1) in neural processing, a brief resting pause that occurs after a neuron has fired; subsequent action potentials cannot occur until the axon returns to its resting state. (2) in human sexuality, a resting period that occurs after orgasm, during which a person cannot achieve another orgasm. (pp. 83, 420)	**período refractario** (1) en el procesamiento neuronal, una breve fase de descanso que se produce después de que una neurona ha disparado. No se pueden producir potenciales subsiguientes de acción hasta que el axón vuelva a su estado de reposo. (2) en la sexualidad humana, fase de descanso que se produce después del orgasmo, en la que el varón es incapaz de tener otro orgasmo. (pp. 83, 420)
regression toward the mean the tendency for extreme or unusual scores or events to fall back (regress) toward the average. (p. 53)	**regresión hacia la media** tendencia hacia las puntuaciones o eventos extremos o poco comunes para así retornar (regresar) hacia el promedio. (p. 53)
reinforcement in operant conditioning, any event that *strengthens* the behavior it follows. (p. 284)	**reforzamiento** según el condicionamiento operante, todo suceso que *fortalezca* el comportamiento al que sigue. (p. 284)
reinforcement schedule a pattern that defines how often a desired response will be reinforced. (p. 287)	**plan de reforzamiento** patrón que define la frecuencia con que se reforzará una respuesta deseada. (p. 287)
relational aggression an act of aggression (physical or verbal) intended to harm a person’s relationship or social standing. (p. 521)	**regresión relacional** acto de agresión (sea física o verbal) que tiene por intención hacerle daño a las relaciones de la persona o a su estatus social. (p. 521)

relative deprivation the perception that one is worse off relative to those with whom one compares oneself. (p. 476)	**privación relativa** impresión de que estamos en peor situación que aquellos con quienes nos comparamos. (p. 476)
relearning a measure of memory that assesses the amount of time saved when learning material again. (p. 327)	**reaprendizaje** medida de memoria que evalúa el tiempo que se ahorra cuando se aprende algo por segunda vez. (p. 327)
reliability the extent to which a test yields consistent results, as assessed by the consistency of scores on two halves of the test, on alternative forms of the test, or on retesting. (p. 636)	**fiabilidad** grado de coherencia de los resultados de una prueba, que se comprueba por la uniformidad de las puntuaciones en las dos mitades de la prueba, en formas distintas de la prueba, o al repetir la prueba. (p. 636)
REM rebound the tendency for REM sleep to increase following REM sleep deprivation. (p. 251)	**rebote de MOR** tendencia al aumento del sueño MOR como consecuencia de la privación del sueño MOR. (p. 251)
REM sleep rapid eye movement sleep; a recurring sleep stage during which vivid dreams commonly occur. Also known as *paradoxical sleep*, because the muscles are relaxed (except for minor twitches) but other body systems are active. (p. 232)	**sueño MOR** sueño de movimiento ocular rápido; etapa recurrente del sueño durante la cual generalmente ocurren sueños gráficos. También se conoce como *sueño paradójico*, porque los músculos están relajados (salvo unos espasmos mínimos) pero los demás sistemas del cuerpo están activos. (p. 232)
repetitive transcranial magnetic stimulation (rTMS) the application of repeated pulses of magnetic energy to the brain; used to stimulate or suppress brain activity. (p. 757)	**estimulación magnética transcraneal repetitiva (EMTR)** aplicación repetitiva de pulsos de energía magnética al cerebro. Se utiliza para estimular o suprimir la actividad cerebral. (p. 757)
replication repeating the essence of a research study, usually with different participants in different situations, to see whether the basic finding can be reproduced. (p. 43)	**replicación** repetir la esencia de un estudio de investigación, por lo general con participantes diferentes y en situaciones diferentes, para ver si las conclusiones básicas se pueden reproducir. (p. 43)
representativeness heuristic estimating the likelihood of events in terms of how well they seem to represent, or	**heurística de la representatividad** estima la probabilidad de cierto evento en función de qué tan bien representan o

match, particular prototypes; may lead us to ignore other relevant information. (p. 372)	corresponden a prototipos particulares; posiblemente nos lleve a ignorar otra información relevante. (p. 372)
repression in psychoanalytic theory, the basic defense mechanism that banishes from consciousness anxiety-arousing thoughts, feelings, and memories. (pp. 355, 581)	**represión** en la teoría del psicoanálisis, el mecanismo básico de defensa por medio del cual el sujeto elimina de su consciente aquellos pensamientos, emociones o recuerdos que le producen ansiedad. (pp. 355, 581)
resilience the personal strength that helps most people cope with stress and recover from adversity and even trauma. (p. 760)	**resiliencia** fuerza personal que ayuda a la mayoría de las personas a asumir con flexibilidad situaciones de estrés y recuperarse de la adversidad e incluso de un trauma. (p. 760)
resistance in psychoanalysis, the blocking from consciousness of anxietyladen material. (p. 723)	**resistencia** en el psicoanálisis, bloquear del consciente aquello que está cargado de ansiedad. (p. 723)
respondent behavior behavior that occurs as an automatic response to some stimulus. (p. 271)	**comportamiento de respuesta** comportamiento que ocurre como respuesta automática a un estímulo. (p. 271)
reticular formation a nerve network that travels through the brainstem into the thalamus and plays an important role in controlling arousal. (p. 102)	**formación reticular** red de nervios que atraviesa el tronco encefálico e ingresa en el tálamo y que desempeña un papel importante en el control de la excitación. (p. 102)
retina the light-sensitive inner surface of the eye, containing the receptor rods and cones plus layers of neurons that begin the processing of visual information. (p. 177)	**retina** superficie en la parte interior del ojo que es sensible a la luz y que contiene los receptores de luz llamados bastoncillos y conos, además de capas de neuronas que inician el procesamiento de la información visual. (p. 177)
retinal disparity a binocular cue for perceiving depth. By comparing retinal images from the two eyes, the brain computes distance—the greater the disparity (difference) between the two images, the closer the object. (p. 189)	**disparidad retiniana** clave binocular para la percepción de la profundidad. Mediante la comparación de las imágenes que provienen de ambos ojos, el cerebro calcula la distancia. Cuanto mayor sea la disparidad (diferencia) entre dos imágenes, más cerca estará el objeto. (p. 189)

retrieval the process of getting information out of memory storage. (p. 329)	**recuperación** proceso de extraer la información que está almacenada en la memoria. (p. 329)
retroactive interference the backward-acting disruptive effect of newer learning on the recall of *old* information. (p. 354)	**interferencia retroactiva** efecto interruptor de algo nuevo que se ha aprendido en la capacidad de recordar información vieja. (p. 354)
retrograde amnesia an inability to retrieve information from one’s past. (p. 351)	**amnesia retrógrada** incapacidad de una persona para recuperar información de su pasado. (p. 351)
reuptake a neurotransmitter’s reabsorption by the sending neuron. (p. 86)	**recaptación** reabsorción de un neurotransmisor por la neurona emisora. (p. 86)
rods retinal receptors that detect black, white, and gray, and are sensitive to movement; necessary for peripheral and twilight vision, when cones don’t respond. (p. 178)	**bastoncillos** receptores de la retina que detectan el negro, el blanco y el gris, y que son sensibles al movimiento; necesarios para la visión periférica y en la penumbra cuando los conos no responden. (p. 178)
role a set of expectations (norms) about a social position, defining how those in the position ought to behave. (pp. 525, 772)	**rol** conjunto de expectativas (normas) acerca de una posición social, que definen la forma en que deben comportarse las personas que ocupan esa posición. (pp. 525, 772)
Rorschach inkblot test the most widely used projective test; a set of 10 inkblots, designed by Hermann Rorschach; seeks to identify people’s inner feelings by analyzing their interpretations of the blots. (p. 584)	**prueba de Rorschach** prueba proyectiva de amplio uso; conjunto de 10 manchas de tinta, diseñado por Hermann Rorschach; busca identificar los sentimientos internos de las personas mediante el análisis de sus interpretaciones de las manchas. (p. 584)
rumination compulsive fretting; *overthinking* our problems and their causes. (p. 693)	**ruminación** preocupación compulsiva; *pensar excesivamente* en nuestros problemas y sus causas. (p. 693)
S	
sampling bias a flawed sampling process that produces an	**sesgo de muestreo** proceso de muestreo fallido que produce una

unrepresentative sample. (p. 47)	muestra no representativa. (p. 47)
savant syndrome a condition in which a person otherwise limited in mental ability has an exceptional specific skill, such as in computation or drawing. (p. 627)	**síndrome de savant** condición según la cual una persona de capacidad mental limitada, cuenta con una destreza excepcional en un campo como la computación o el dibujo. (p. 627)
scaffold a framework that offers children temporary support as they develop higher levels of thinking. (p. 503)	**andamiaje** estructura que ofrece apoyo provisional a los niños mientras desarrollan un orden más alto de pensamiento. (p. 503)
scapegoat theory the theory that prejudice offers an outlet for anger by providing someone to blame. (p. 797)	**teoría del chivo expiatorio** teoría que expone que el prejuicio ofrece un escape para el enojo porque nos brinda a alguien a quien culpar. (p. 797)
scatterplot a graphed cluster of dots, each of which represents the values of two variables. The slope of the points suggests the direction of the relationship between the two variables. The amount of scatter suggests the strength of the correlation (little scatter indicates high correlation). (p. 51)	**gráfico de aspersión** conjunto de datos graficados, cada uno de los cuales representa los valores de dos variables. La pendiente de los puntos sugiere el sentido de la relación entre las dos variables. El nivel de aspersión sugiere la fuerza de la correlación (un bajo nivel de aspersión indica alta correlación). (p. 51)
schema a concept or framework that organizes and interprets information. (p. 498)	**esquema** concepto o marco referencial que organiza e interpreta la información. (p. 498)
schizophrenia a disorder characterized by delusions, hallucinations, disorganized speech, and/or diminished, inappropriate emotional expression. (p. 699)	**esquizofrenia** trastorno caracterizado por delirios, alucinaciones, habla desorganizada y/o expresión emocional disminuida o inapropiada. (p. 699)
secondary sex characteristics nonreproductive sexual traits, such as female breasts and hips, male voice quality, and body hair. (p. 546)	**características secundarias del sexo** rasgos sexuales no relacionados con la reproducción, tales como los senos y las caderas de las mujeres, la calidad de la voz del varón, y el vello corporal. (p. 546)
secure attachment demonstrated by infants who comfortably explore environments in the presence of their caregiver, show only temporary distress	**apego seguro** exhibido por infantes que exploran su entorno cómodamente en la presencia de su cuidador, sólo muestran angustia temporal

when the caregiver leaves, and find comfort in the caregiver's return. (p. 511)	en ausencia del cuidador, y se consuelan con el retorno del cuidador. (p. 511)
selective attention the focusing of conscious awareness on a particular stimulus. (p. 159)	**atención selectiva** capacidad de enfocar la consciencia en un estímulo en particular. (p. 159)
self in contemporary psychology, assumed to be the center of personality, the organizer of our thoughts, feelings, and actions. (p. 611)	**yo** imagen que tenemos de nosotros mismos y entendimiento de quiénes somos. Según la psicología moderna, el concepto de que éste es el centro de la personalidad, que organiza los pensamientos, los sentimientos y las acciones. (p. 611)
self-actualization according to Maslow, one of the ultimate psychological needs that arises after basic physical and psychological needs are met and self-esteem is achieved; the motivation to fulfill one's potential. (p. 591)	**autorrealización** según Maslow, necesidad psicológica que surge después de satisfacer las necesidades físicas y psicológicas y de lograr la autoestima; motivación para realizar nuestro potencial pleno. (p. 591)
self-concept all our thoughts and feelings about ourselves in answer to the question, "Who am I?" (pp. 515, 592)	**concepto de uno mismo** todo lo que pensamos y sentimos acerca de nosotros mismos cuando respondemos a la pregunta: "¿Quién soy?". (pp. 515, 592)
self-control the ability to control impulses and delay short-term gratification for greater long-term rewards. (p. 309)	**autocontrol** capacidad de controlar los impulsos y demorar la gratificación a corto plazo con el fin de obtener mayores recompensas a largo plazo. (p. 309)
self-disclosure the act of revealing intimate aspects of ourselves to others. (p. 814)	**revelación personal** revelación a los demás de cosas íntimas de nuestro ser. (p. 814)
self-efficacy one's sense of competence and effectiveness. (p. 612)	**autoeficacia** nuestros sentimientos de competencia y eficacia. (p. 612)
self-esteem one's feelings of high or low self-worth. (p. 612)	**autoestima** los sentimientos propios de alto o bajo valor. (p. 612)
self-fulfilling prophecy	**profecía autorrealizada**

a belief that leads to its own fulfillment. (p. 820)	creencia que conduce a su propia realización. (p. 820)
self-serving bias a readiness to perceive oneself favorably. (p. 614)	**sesgo autocomplaciente** disposición para percibirnos a nosotros mismos de manera favorable. (p. 614)
self-transcendence according to Maslow, the striving for identity, meaning, and purpose beyond the self. (p. 591)	**autotrascendencia** según Maslow, esfuerzo por alcanzar una identidad, un sentido y un propósito que vaya más allá de uno mismo. (p. 591)
semantic memory explicit memory of facts and general knowledge; one of our two conscious memory systems (the other is *episodic memory*). (p. 340)	**memoria semántica** memoria explícita de hechos y conocimientos generales. Uno de los dos sistemas de memoria conscientes (el otro es la memoria episódica). (p. 340)
sensation the process by which our sensory receptors and nervous system receive and represent stimulus energies from our environment. (p. 158)	**sensación** proceso mediante el cual los receptores sensoriales y el sistema nervioso reciben las energías de los estímulos provenientes de nuestro entorno. (p. 158)
sensorimotor stage in Piaget’s theory, the stage (from birth to nearly 2 years of age) during which infants know the world mostly in terms of their sensory impressions and motor activities. (p. 499)	**etapa sensoriomotriz** en la teoría de Piaget, la etapa (de los 0 a los 2 años de edad) durante la cual los bebés conocen el mundo principalmente en términos de sus impresiones sensoriales y actividades motoras. (p. 499)
sensorineural hearing loss hearing loss caused by damage to the cochlea’s receptor cells or to the auditory nerves; the most common form of hearing loss, also called *nerve deafness*. (p. 200)	**pérdida de la audición sensorineuronal** sordera causada por daños a la células receptoras de la cóclea o a los nervios de la audición; la forma más común de sordera. También se le dice *sordera nerviosa*. (p. 200)
sensory (afferent) neurons neurons that carry incoming information from the body’s tissues and sensory receptors to the brain and spinal cord. (p. 93)	**neurona sensorial (aferente)** neurona que conduce la información que le llega desde los tejidos del cuerpo y los receptores sensoriales al cerebro y la médula espinal. (p. 93)
sensory adaptation diminished sensitivity as a consequence of constant stimulation. (p. 165)	**adaptación sensorial** disminución en la sensibilidad como respuesta a la estimulación constante. (p.

	165)
sensory interaction the principle that one sense may influence another, as when the smell of food influences its taste. (p. 214)	**interacción sensorial** principio según el cual un sentido puede influir en otro, como cuando el olor de la comida influye en su sabor. (p. 214)
sensory memory the immediate, very brief recording of sensory information in the memory system. (p. 329)	**memoria sensorial** registro breve e inmediato de la información sensorial en el sistema de la memoria. (p. 329)
sensory receptors sensory nerve endings that respond to stimuli. (p. 158)	**receptores sensoriales** terminales nerviosas sensoriales que responden a estímulos. (p. 158)
sequential processing processing one aspect of a problem at a time; generally used to process new information or to solve difficult problems. (p. 126)	**procesamiento secuencial** procesamiento de un aspecto de un problema a la vez; se utiliza cuando centramos la atención en tareas nuevas o complejas. (p. 126)
serial position effect our tendency to recall best the last *(recency effect)* and first *(primacy effect)* items in a list. (p. 347)	**efecto de posición serial** tendencia a recordar con mayor facilidad los elementos del comienzo (*efecto de primacía*) y el final (*efecto de recencia*) de una lista. (p. 347)
set point the point at which your “weight thermostat” may be set. When your body falls below this weight, increased hunger and a lowered metabolic rate may combine to restore lost weight. (p. 411)	**punto fijo** punto de supuesto equilibrio en el “termostato del peso” de una persona. Cuando el cuerpo alcanza un peso por debajo de este punto, se produce un aumento en el hambre y una disminución en el índice metabólico, los cuales pueden actuar para restablecer el peso perdido. (p. 411)
sex in psychology, the biologically influenced characteristics by which people define *male* and *female*. (p. 520)	**sexo** en psicología, las características biológicas por las cuales la sociedad define al hombre y la mujer. (p. 520)
sexual orientation our enduring sexual attraction, usually toward members of our own sex (homosexual orientation) or the other sex (heterosexual orientation); variations include	**orientación sexual** nuestra atracción sexual principal hacia miembros de nuestro mismo sexo (orientación homosexual), del sexo opuesto (orientación heterosexual) o de ambos sexos

attraction toward both sexes (bisexual orientation). (p. 549)	(orientación bisexual). (p. 549)
sexual response cycle the four stages of sexual responding described by Masters and Johnson—excitement, plateau, orgasm, and resolution. (p. 419)	**ciclo de respuesta sexual** las cuatro etapas de respuesta sexual descritas por Masters y Johnson: excitación, meseta, orgasmo y resolución. (p. 419)
shallow processing encoding on a basic level, based on the structure or appearance of words. (p. 335)	**procesamiento superficial** codificación en un nivel básico, según la estructura o la apariencia de las palabras. (p. 335)
shaping an operant conditioning procedure in which reinforcers guide behavior toward closer and closer approximations of the desired behavior. (p. 284)	**modelamiento** procedimiento del condicionamiento operante en el cual los reforzadores conducen una acción con aproximaciones sucesivas hasta lograr el comportamiento deseado. (p. 284)
short-term memory activated memory that holds a few items briefly, such as digits of a phone number while calling, before the information is stored or forgotten. (p. 329)	**memoria a corto plazo** memoria activada que retiene algunos elementos por un corto tiempo, tales como los siete dígitos de un número telefónico mientras se marca, antes de que la información se almacene o se olvide. (p. 329)
signal detection theory a theory predicting how and when we detect the presence of a faint stimulus *(signal)* amid background stimulation *(noise)*. Assumes there is no single absolute threshold and that detection depends partly on a person's experience, expectations, motivation, and alertness. (p. 163)	**teoría de la detección de señales** teoría que predice cómo y cuando detectamos la presencia de un estímulo débil (*señal*) cuando hay estímulos de fondo (*ruido*). Supone que no hay un umbral absoluto y que la detección depende en parte en las experiencias, expectativas, motivaciones y estado de alerta de la persona. (p. 163)
skewed distribution a representation of scores that lack symmetry around their average value. (p. 67)	**sesgo de distribución** representación de puntajes que carece de simetría alrededor de su valor promedio. (p. 67)
sleep a periodic, natural loss of consciousness —as distinct from unconsciousness resulting	**sueño** pérdida del conocimiento periódica y natural; a diferencia de la inconsciencia que

from a coma, general anesthesia, or hibernation. (Adapted from Dement, 1999.) (p. 231)	puede resultar del estado de coma, de la anestesia general o de la hibernación. (Adaptado de Dement, 1999.) (p. 231)
sleep apnea a sleep disorder characterized by temporary cessations of breathing during sleep and repeated momentary awakenings. (p. 245)	**apnea del sueño** trastorno del sueño en el que se interrumpe repetidamente la respiración hasta que el nivel de oxígeno en la sangre disminuye tanto que la persona tiene que despertarse para respirar. (p. 245)
social anxiety disorder intense fear and avoidance of social situations. (Formerly called *social phobia*.) (p. 677)	**trastorno de ansiedad social** miedo intenso y evasión de situaciones sociales. (Conocido anteriormente como *fobia social*). (p. 677)
social clock the culturally preferred timing of social events such as marriage, parenthood, and retirement. (p. 565)	**reloj social** manera que la sociedad prefiere para marcar el tiempo adecuado de los eventos sociales, tales como el matrimonio, la paternidad y la jubilación. (p. 565)
social exchange theory the theory that our social behavior is an exchange process, the aim of which is to maximize benefits and minimize costs. (p. 818)	**teoría de intercambio social** teoría según la cual nuestro comportamiento se encuentra en un estado de intercambio, cuyo fin es maximizar los beneficios y minimizar los costos. (p. 818)
social facilitation improved performance on simple or well-learned tasks in the presence of others. (p. 784)	**facilitación social** mejoramiento del desempeño en funciones sencillas o bien aprendidas en la presencia de otros. (p. 784)
social identity the "we" aspect of our self-concept; the part of our answer to "Who am I?" that comes from our group memberships. (p. 539)	**identidad social** aspecto de "nosotros" dentro de nuestro concepto de nosotros mismos; parte de nuestra respuesta a "¿Quién soy?" que proviene de nuestra pertenencia a grupos. (p. 539)
social learning theory the theory that we learn social behavior by observing and imitating and by being rewarded or punished. (p. 525)	**teoría de aprendizaje social** teoría que señala que aprendemos la conducta social observando e imitando, y al ser recompensados o castigados. (p. 525)
social loafing the tendency for people in a group to exert less effort when pooling their efforts toward	**holgazanería social** tendencia de las personas en un grupo de realizar menos esfuerzo cuando juntan sus

attaining a common goal than when individually accountable. (p. 785)	esfuerzos para lograr una meta común que cuando son responsables individualmente. (p. 785)
social psychology the scientific study of how we think about, influence, and relate to one another. (pp. 24, 768)	**psicología social** estudio científico de cómo nos relacionamos con los demás y cómo influimos y pensamos en ellos. (pp. 24, 768)
social script a culturally modeled guide for how to act in various situations. (pp. 146, 804)	**guión social** guía modelada culturalmente acerca de cómo actuar en diversas situaciones. (pp. 146, 804)
social trap a situation in which the conflicting parties, by each pursuing their self-interest rather than the good of the group, become caught in mutually destructive behavior. (p. 819)	**trampa social** situación en la cual las partes en conflicto, al perseguir cada uno su interés propio y no el del grupo, caen en comportamientos mutuamente destructivos. (p. 819)
social-cognitive perspective views behavior as influenced by the interaction between people’s traits (including their thinking) and their social context. (p. 606)	**perspectiva sociocognitiva** contempla al comportamiento como susceptible a la influencia de la interacción entre los rasgos de las personas (que incluye su pensamiento) y su contexto social. (p. 606)
social-cultural psychology the study of how situations and cultures affect our behavior and thinking. (p. 18)	**psicología socio-cultural** estudio de cómo las situaciones y las culturas afectan nuestro comportamiento y pensamiento. (p. 18)
social-responsibility norm an expectation that people will help those needing their help. (p. 819)	**norma de responsabilidad social** expectativa según la cual las personas ayudarán a aquellos que necesitan ayuda. (p. 819)
somatic nervous system the division of the peripheral nervous system that controls the body’s skeletal muscles. Also called the *skeletal nervous system.* (p. 93)	**sistema nervioso somático** división del sistema nervioso periférico que controla los músculos esqueléticos del cuerpo. También llamado *sistema nervioso esquelético*. (p. 93)
somatic symptom disorder a psychological disorder in which the symptoms take a somatic (bodily) form without apparent physical cause. (Formerly called *somatoform disorder;* see *conversion disorder* and *illness anxiety disorder*.) (p.	**trastorno de síntomas somáticos** trastorno psicológico donde los síntomas toman una forma somática (corporal) sin causa física aparente. (Conocido anteriormente como *trastorno somatomorfo*; ver *trastorno de conversión* y *trastorno de*

707)	*ansiedad de enfermedad*). (p. 707)
somatosensory cortex an area at the front of the parietal lobes that registers and processes body touch and movement sensations. (p. 113)	**corteza somatosensorial** región de la corteza cerebral en la parte delantera de los lóbulos parietales. Registra y procesa el tacto y las sensaciones de movimiento. (p. 113)
source amnesia faulty memory for how, when, or where information was learned or imagined. (Also called *source misattribution.*) Source amnesia, along with the misinformation effect, is at the heart of many false memories. (p. 358)	**amnesia de la fuente** recuerdo errado de cómo, cuándo o dónde se aprendió o se imaginó la información. (Conocida también como *atribución errónea*). La amnesia de la fuente, junto con el efecto de información errónea, son la razón de muchos recuerdos falsos. (p. 358)
spacing effect the tendency for *distributed* study or practice to yield better long-term retention than is achieved through *massed* study or practice. (p. 334)	**efecto de memoria espaciada** tendencia en la que el estudio o la práctica *distribuida* rinde mejor retención a largo plazo que el estudio o práctica *en masa*. (p. 334)
spermarche [sper-MAR-key] the first ejaculation. (p. 547)	**espermarca** primera eyaculación. (p. 547)
split brain a condition resulting from surgery that isolates the brain's two hemispheres by cutting the fibers (mainly those of the corpus callosum) connecting them. (p. 120)	**cerebro dividido** condición en la que los dos hemisferios cerebrales se privan de la comunicación mediante el corte quirúrgico de las fibras que los conectan (principalmente las del cuerpo calloso). (p. 120)
spontaneous recovery the reappearance, after a pause, of an extinguished conditioned response. (p. 276)	**recuperación espontánea** reaparición, después de una pausa, de una respuesta condicionada extinguida. (p. 276)
spotlight effect overestimating others' noticing and evaluating our appearance, performance, and blunders (as if we presume a spotlight shines on us). (p. 611)	**efecto reflector** sobreestimar cuánto las otras personas perciben y evalúan nuestra apariencia, desempeño y errores (como si supusiéramos que hay un reflector sobre nosotros). (p. 611)
SQ3R a study method incorporating five steps: *S*urvey, *Q*uestion, *R*ead, *R*etrieve, *R*eview. (p. 20)	**SQ3R** método de estudio en el que se siguen cinco pasos: Inspeccionar, Preguntar, Leer, Recitar, Repasar (*S*urvey, *Q*uestion, *R*ead,

	*R*etrieve, *R*eview, en inglés). (p. 20)
standard deviation a computed measure of how much scores vary around the mean score. (p. 68)	**desviación estándar** medición computada de cuánto varía cierta puntuación con respecto a la puntuación media. (p. 68)
standardization defining uniform testing procedures and meaningful scores by comparison with the performance of a pretested group. (p. 635)	**estandarización** definir procedimientos de medición uniformes y puntuaciones significativos mediante la comparación del desempeño de un grupo examinado con anterioridad. (p. 635)
Stanford-Binet the widely used American revision (by Terman at Stanford University) of Binet's original intelligence test. (p. 634)	**Stanford-Binet** revisión norteamericana (por Terman en la Universidad de Stanford) de la prueba original de inteligencia de Binet. Esta prueba es de uso extenso. (p. 634)
statistical significance a statistical statement of how likely it is that an obtained result occurred by chance. (p. 71)	**significancia estadística** declaración estadística de la probabilidad de que un resultado obtenido haya sido producto del azar.
stereotype a generalized (sometimes accurate but often overgeneralized) belief about a group of people. (p. 792)	**estereotipo** creencia (a veces acertada, pero frecuentemente demasiado generalizada) sobre las características de un grupo. (p. 792)
stereotype threat a self-confirming concern that one will be evaluated based on a negative stereotype. (p. 657)	**amenaza de estereotipos** preocupación autoconfirmada de que nos evaluarán con base en un estereotipo negativo. (p. 657)
stimulants drugs (such as caffeine, nicotine, and the more powerful cocaine, amphetamines, methamphetamine, and Ecstasy) that excite neural activity and speed up body functions. (p. 257)	**estimulantes** fármacos (tales como la cafeína, la nicotina y sustancias más poderosas como cocaína, anfetaminas, metanfetamina y éxtasis) que excitan la actividad neuronal y aceleran las funciones corporales. (p. 257)
stimulus any event or situation that evokes a response. (p. 271)	**estímulo** todo suceso o situación que provoca una respuesta. (p. 271)

storage the process of retaining encoded information over time. (p. 329)	**almacenamiento** retención a través del tiempo de información codificada. (p. 329)
strange situation a procedure for studying child-caregiver attachment; a child is placed in an unfamiliar environment while their caregiver leaves and then returns, and the child's reactions are observed. (p. 511)	**situación desconocida** procedimiento para estudiar el apego entre niño y cuidador; se coloca al niño en un entorno desconocido mientras su cuidador se va y regresa. Entretanto se observan las reacciones del niño. (p. 511)
stranger anxiety the fear of strangers that infants commonly display, beginning by about 8 months of age. (p. 509)	**miedo a los extraños** miedo a los extraños que manifiestan los bebés normalmente a partir de alrededor de los 8 meses de edad. (p. 509)
stress the process by which we perceive and respond to certain events, called *stressors*, that we appraise as threatening or challenging. (p. 450)	**estrés** proceso mediante el cual percibimos y respondemos a ciertos eventos llamados estresores, los cuales evaluamos como amenazantes o desafiantes. (p. 450)
structuralism an early school of thought promoted by Wundt and Titchener; used introspection to reveal the structure of the human mind. (p. 7)	**estructuralismo** escuela temprana de pensamiento promovida por Wundt y Titchener; usaba la introspección para revelar la estructura de la mente humana. (p. 7)
subjective well-being self-perceived happiness or satisfaction with life. Used along with measures of objective well-being (for example, physical and economic indicators) to evaluate people's quality of life. (p. 473)	**bienestar subjetivo** felicidad o satisfacción con la vida de uno mismo. Se emplea junto con medidas de bienestar objetivas (por ejemplo, con indicadores físicos y económicos) para evaluar nuestra calidad de vida. (p. 473)
subliminal below one's absolute threshold for conscious awareness. (p. 163)	**subliminal** aquello que ocurre por debajo de nuestro umbral absoluto de la consciencia. (p. 163)
substance use disorder a disorder characterized by continued substance craving and use despite significant life disruption and/or physical risk. (p. 253)	**trastornos causados por el uso de estupefacientes** trastorno caracterizado por el deseo prolongado de consumir una sustancia a pesar de los efectos negativos en la vida de quienes abusan de las sustancias y/o los riesgos físicos que implican. (p. 253)
superego	**supergo**

the part of personality that, according to Freud, represents internalized ideals and provides standards for judgment (the conscience) and for future aspirations. (p. 580)	en el psicoanálisis freudiano, componente de la personalidad que representa ideales internalizados y proporciona parámetros de juicio (la consciencia) y para fijarse metas futuras. (p. 580)
superordinate goals shared goals that override differences among people and require their cooperation. (p. 821)	**metas comunes** metas compartidas que hacen caso omiso de las diferencias entre las personas y que requieren su cooperación. (p. 821)
suprachiasmatic nucleus (SCN) a pair of cell clusters in the hypothalamus that controls circadian rhythm. In response to light, the SCN causes the pineal gland to adjust melatonin production, thus modifying our feelings of sleepiness. (p. 235)	**núcleo supraquiasmático (NSQ)** par de grupos de células en el hipotálamo que controlan el ritmo circadiano. Como respuesta a la luz, el núcleo supraquiasmático ajusta la producción de melatonina, modificando de esta manera los niveles de somnolencia. (p. 235)
survey a descriptive technique for obtaining the self-reported attitudes or behaviors of a particular group, usually by questioning a representative, *random sample* of the group. (p. 47)	**encuesta** técnica descriptiva para obtener actitudes o conductas del grupo autoinformadas por las personas; generalmente mediante preguntas que se le plantean a una *muestra aleatoria* y representativa de dicho grupo. (p. 47)
sympathetic nervous system the division of the autonomic nervous system that arouses the body, mobilizing its energy. (p. 93)	**sistema nervioso simpático** subdivisión del sistema nervioso autonómico que en despierta al cuerpo y moviliza su energía. (p. 93)
synapse [SIN-aps] the junction between the axon tip of the sending neuron and the dendrite or cell body of the receiving neuron. The tiny gap at this junction is called the *synaptic gap* or *synaptic cleft*. (p. 85)	**sinapsis** intersección entre el extremo del axón de una neurona que envía un mensaje y la dendrita o cuerpo celular de la neurona receptora. El pequeño espacio entre estos puntos de contacto se denomina *brecha sináptica* o *hendidura sináptica*. (p. 85)
systematic desensitization a type of exposure therapy that associates a pleasant relaxed state with gradually increasing anxiety-triggering stimuli. Commonly used to treat phobias. (p. 730)	**desensibilización sistemática** tipo de terapia de exposición en la cual se asocia un estado tranquilo y agradable con estímulos que van aumentando paulatinamente y que provocan ansiedad. De uso común para tratar fobias. (p. 730)
T	

telegraphic speech early speech stage in which a child speaks like a telegram—“go car”—using mostly nouns and verbs. (p. 384)	**habla telegráfica** etapa temprana del habla en la cuál los niños hablan como telegrama —“va carro”— mediante sustantivos y verbos principalmente. (p. 384)
temperament a person’s characteristic emotional reactivity and intensity. (p. 511)	**temperamento** reactividad e intensidad emocionales características de una persona. (p. 511)
temporal lobes the portion of the cerebral cortex lying roughly above the ears; includes the auditory areas, each receiving information primarily from the opposite ear. (p. 110)	**lóbulos temporales** región de la corteza cerebral ubicada aproximadamente encima de las orejas; incluye las áreas auditivas, que reciben información principalmente del oído opuesto. (p. 110)
tend-and-befriend response under stress, people (especially women) often provide support to others (tend) and bond with and seek support from others (befriend). (p. 455)	**respuesta de cuidarse y amigarse** en situaciones de estrés, las personas (sobre todo las mujeres) a menudo se dan apoyo (se cuidan), a la vez que forman vínculos y buscan apoyo de otros (amigarse). (p. 455)
teratogens (literally, “monster makers”) agents, such as chemicals and viruses, that can reach the embryo or fetus during prenatal development and cause harm. (p. 490)	**teratógeno** (literalmente, “creadores de monstruos”) agente, podría ser químico o viral, que pueden afectar al embrión o al feto durante el desarrollo prenatal, produciéndole daño. (p. 490)
terror-management theory a theory of death-related anxiety; explores people’s emotional and behavioral responses to reminders of their impending death. (p. 588)	**teoría del manejo del terror** teoría de la ansiedad relacionada con la muerte; explora las respuestas emotivas y conductuales de las personas ante recordatorios de su muerte inevitable. (p. 588)
testing effect enhanced memory after retrieving, rather than simply rereading, information. Also sometimes referred to as a *retrieval practice effect* or *test-enhanced learning*. (pp. 20, 335)	**efecto de prueba** recuerdo aumentado luego de recuperar la información, en lugar de simplemente volver a leerla. También conocido como *efecto de práctica de recuperación* o *aprendizaje intensificado por pruebas*. (pp. 20, 335)
testosterone the most important male sex hormone. Both males and females have it, but the additional testosterone in males stimulates the growth of the male sex organs during the fetal period	**testosterona** la hormona sexual masculina más importante. La tienen tanto los varones como las mujeres pero la cantidad adicional en los varones estimula el crecimiento de los

and the development of the male sex characteristics during puberty. (pp. 418, 545)	órganos sexuales masculinos durante el período fetal y el desarrollo de las características sexuales masculinas secundarias en la pubertad. (pp. 418, 545)
thalamus [THAL-uh-muss] the brain's sensory control center, located on top of the brainstem; it directs messages to the sensory receiving areas in the cortex and transmits replies to the cerebellum and medulla. (p. 102)	**tálamo** centro sensorial de control del cerebro ubicado encima del tronco encefálico; dirige mensajes sensoriales a la corteza cerebral y transmite respuestas al cerebelo y la médula. (p. 102)
THC the major active ingredient in marijuana; triggers a variety of effects, including mild hallucinations. (p. 262)	**THC** principal sustancia activa que se encuentra en la marihuana, produce distintos efectos, inclusive alucinaciones menores. (p. 262)
Thematic Apperception Test (TAT) a projective test in which people express their inner feelings and interests through the stories they make up about ambiguous scenes. (p. 584)	**prueba de apercepción temática (PAT)** prueba proyectiva en la que el individuo expresa sus sentimientos e intereses internos mediante historias que inventa en torno a escenas ambiguas. (p. 584)
theory an explanation using an integrated set of principles that organizes observations and predicts behaviors or events. (p. 42)	**teoría** explicación que emplea principios que organizan observaciones y predicen comportamientos o sucesos. (p. 42)
theory of mind people's ideas about their own and others' mental states—about their feelings, perceptions, and thoughts, and the behaviors these might predict. (p. 501)	**teoría de la mente** conceptos que tienen las personas acerca de sus propios procesos mentales y de los de los demás; es decir, de sus sentimientos, percepciones y pensamientos y de los comportamientos que estos podrían predecir. (p. 501)
therapeutic alliance a bond of trust and mutual understanding between a therapist and client, who work together constructively to overcome the client's problem. (p. 747)	**alianza terapéutica** vínculo de confianza y comprensión mutua que se establece entre el terapeuta y el cliente, que trabajan juntos de manera constructiva para superar el problema del cliente. (p. 747)
threshold the level of stimulation required to trigger a neural impulse. (p. 83)	**umbral** nivel de estimulación requerido para activar un impulso neuronal. (p. 83)
token economy	**economía de fichas**

an operant conditioning procedure in which people earn a token for exhibiting a desired behavior and can later exchange tokens for privileges or treats. (p. 732)	procedimiento del condicionamiento operante en el que las personas se ganan una ficha cuando exhiben un comportamiento deseado y luego pueden intercambiar las fichas ganadas por privilegios o para darse algún gusto. (p. 732)
tolerance the diminishing effect with regular use of the same dose of a drug, requiring the user to take larger and larger doses before experiencing the drug’s effect. (p. 255)	**tolerancia** disminución del efecto con el uso regular de la misma dosis de un fármaco, lo que requiere que el usuario tome dosis cada vez mayores para poder experimentar el efecto del fármaco. (p. 255)
top-down processing information processing guided by higher-level mental processes, as when we construct perceptions drawing on our experience and expectations. (p. 159)	**procesamiento de arriba hacia abajo** procesamiento de la información orientado por procesos mentales de alto nivel, como cuando construimos percepciones basándonos en nuestras vivencias y expectativas. (p. 159)
trait a characteristic pattern of behavior or a disposition to feel and act in certain ways, as assessed by self-report inventories and peer reports. (p. 596)	**rasgo** patrón de comportamiento característico o disposición a sentirse y actuar de cierta forma, según se evalúa en los inventarios de autoinformes e informes de pares. (p. 596)
transduction conversion of one form of energy into another. In sensation, the transforming of stimulus energies, such as sights, sounds, and smells, into neural impulses our brain can interpret. (p. 162)	**transducción** transformación de un tipo de energía en otro. En las sensaciones, transformación de las energías de los estímulos, tales como las imágenes, los sonidos y los olores, en impulsos neuronales que el cerebro tiene la capacidad de interpretar. (p. 162)
transference in psychoanalysis, the patient’s transfer to the analyst of emotions linked with other relationships (such as love or hatred for a parent). (p. 724)	**transferencia** en el psicoanálisis, la transferencia de emociones ligadas a otras relaciones, del paciente al analista (tales como el amor o el odio hacia el padre o la madre). (p. 724)
transgender an umbrella term describing people whose gender identity or expression differs from that associated with their birth-designated sex. (p. 526)	**transgénero** término genérico que describe a personas cuya identidad o expresión de género difiere de la que se asocia con su sexo al nacer. (p. 526)

two-factor theory the Schachter-Singer theory that to experience emotion one must (1) be physically aroused and (2) cognitively label the arousal. (p. 434)	**teoría de los dos factores** teoría de Schachter y Singer que propone que para experimentar emociones debemos (1) recibir estimulación física y (2) identificar el estímulo a nivel cognitivo. (p. 434)
two-word stage beginning about age 2, the stage in speech development during which a child speaks mostly in two-word statements. (p. 384)	**etapa de dos palabras** a partir de los 2 años de edad, etapa del desarrollo del lenguaje durante la cual el niño emite mayormente frases de dos palabras. (p. 384)
Type A Friedman and Rosenman’s term for competitive, hard-driving, impatient, verbally aggressive, and anger-prone people. (p. 459)	**Tipo A** término de Friedman y Rosenman para referirse a las personas competitivas, compulsivas, impacientes, verbalmente agresivas y con tendencia a enojarse. (p. 459)
Type B Friedman and Rosenman’s term for easygoing, relaxed people. (p. 459)	**Tipo B** término de Friedman y Rosenman para referirse a las personas tolerantes, relajadas y tranquilas. (p. 459)
U	
unconditional positive regard a caring, accepting, nonjudgmental attitude, which Carl Rogers believed would help clients develop self-awareness and self-acceptance. (pp. 592, 726)	**consideración positiva incondicional** actitud de cuidado, aceptación y parcialidad. Según Rogers, así los clientes desarrollarían consciencia y aceptación de sí mismos. (pp. 592, 726)
unconditioned response (UR) in classical conditioning, an unlearned, naturally occurring response (such as salivation) to an unconditioned stimulus (US) (such as food in the mouth). (p. 274)	**respuesta incondicionada (RI)** en el condicionamiento clásico, la respuesta no aprendida e innata que es producida por un estímulo incondicionado (EI) (como la salivación cuando la comida está en la boca). (p. 274)
unconditioned stimulus (US) in classical conditioning, a stimulus that unconditionally—naturally and automatically—triggers an unconditioned response UR). (p. 274)	**estímulo incondicionado (EI)** en el condicionamiento clásico, estímulo que provoca una respuesta incondicionalmente (RI) y de manera natural y automática. (p. 274)
unconscious according to Freud, a reservoir of mostly	**inconsciente** según Freud, un depósito de pensamientos,

unacceptable thoughts, wishes, feelings, and memories. According to contemporary psychologists, information processing of which we are unaware. (p. 579)	deseos, sentimientos y recuerdos, en su mayoría inaceptables. Según los psicólogos contemporáneos, el procesamiento de información del cual no tenemos consciencia. (p. 579)
V	
validity the extent to which a test or experiment measures or predicts what it is supposed to. (See also *content validity* and *predictive validity*.) (pp. 56, 636)	**validez** grado en que una prueba mide o predice lo que se supone debe medir o predecir. (Ver también *validez del contenido* y *validez predictiva*.) (pp. 56, 636)
variable anything that can vary and is feasible and ethical to measure. (p. 51)	**variable** todo aquello que varía y que es viable y ético para ser medido. (p. 51)
variable-interval schedule in operant conditioning, a reinforcement schedule that reinforces a response at unpredictable time intervals. (p. 288)	**calendario de intervalo variable** según el condicionamiento operante, calendario de reforzamientos que refuerza una respuesta en intervalos de tiempo impredecibles. (p. 288)
variable-ratio schedule in operant conditioning, a reinforcement schedule that reinforces a response after an unpredictable number of responses. (p. 288)	**plan de proporción variable** en el condicionamiento operante, plan de reforzamientos que refuerza una respuesta después de un número impredecible de respuestas. (p. 288)
vestibular sense our sense of body movement and position that enables our sense of balance. (p. 213)	**sentido vestibular** sentido de movimiento y posición del cuerpo que habilita nuestro sentido de equilibrio (p. 213)
virtual reality exposure therapy a counterconditioning technique that treats anxiety through creative electronic simulations in which people can safely face their greatest fears, such as airplane flying, spiders, or public speaking. (p. 730)	**terapia de exposición a una realidad virtual** técnica del contracondicionamiento que trata la ansiedad mediante estimulaciones electrónicas creativas en en las cuales las personas enfrentan a sus temores más grandes, como volar en avión, ver una araña o hablar en público. (p. 730)
visual cliff a laboratory device for testing depth perception in infants and young animals. (p. 189)	**precipicio visual** dispositivo del laboratorio con el que se examina la percepción de profundidad en los bebés y en animales de corta edad. (p. 189)

W	
wavelength the distance from the peak of one light or sound wave to the peak of the next. Electromagnetic wavelengths vary from the short blips of gamma rays to the long pulses of radio transmission. (p. 177)	**longitud de onda** distancia entre la cresta de una onda de luz o de sonido y la cresta de la siguiente onda. La longitud de las ondas electromagnéticas varían entre la señal corta de los rayos gamma y los pulsos largos de la radio transmisión. (p. 177)
Weber’s law the principle that, to be perceived as different, two stimuli must differ by a constant minimum percentage (rather than a constant amount). (p. 165)	**ley de Weber** principio que sostiene que para que dos estímulos se perciban como distintos, estos deben diferir por un porcentaje mínimo constante (en vez de por una cantidad constante).165)
Wechsler Adult Intelligence Scale (WAIS) the WAIS and its companion versions for children are the most widely used intelligence tests; they contain verbal and performance (nonverbal) subtests. (p. 635)	**escala de la Inteligencia de Wechsler para adultos (EIWA)** la prueba EIWA y su versión adaptada para niños son las pruebas de inteligencia más ampliamente utilizadas. Incluyen subpruebas verbales y de desempeño (no verbales). (p. 635)
Wernicke’s area a brain area involved in language comprehension and expression; usually in the left temporal lobe. (p. 388)	**área de Wernicke** parte del cerebro generalmente ubicada en el lóbulo temporal izquierdo, que participa en la comprensión y la expresión del lenguaje, y que controla la recepción del mismo. (p. 388)
withdrawal the discomfort and distress that follow discontinuing an addictive drug or behavior. (p. 255)	**síndrome de abstinencia** la incomodidad y angustia que resulta cuando se deja de utilizar un estupefaciente adictivo o se suspende una conducta. (p. 255)
working memory a newer understanding of short-term memory that adds conscious, active processing of incoming auditory and visual information, and of information retrieved from long-term memory. (p. 329)	**memoria operativa** entendimiento más reciente de la memoria a corto plazo que añade el procesamiento consciente y activo de información auditiva y visual-espacial, y de información recuperada de la memoria a largo plazo. (p. 329)
X	

X chromosome the sex chromosome found in both males and females. Females typically have two X chromosomes; males typically have one. An X chromosome from each parent produces a female child. (p. 545)	**cromosoma X** cromosoma del sexo que se encuentra en el varón y en la mujer. Las mujeres por lo general tienen dos cromosomas X; los hombres por lo general tienen un cromosoma X y un cromosoma Y. Con un cromosoma X del padre y otro de la madre, se produce una mujer. (p. 545)
Y	
Y chromosome the sex chromosome typically found only in males. When paired with an X chromosome from the mother, it produces a male child. (p. 545)	**cromosoma Y** cromosoma del sexo que solamente se halla en los hombres. Cuando se aparea con un cromosoma X de la madre, produce un varón. (p. 545)
Yerkes-Dodson law the principle that performance increases with arousal only up to a point, beyond which performance decreases. (p. 404)	**Ley de Yerkes-Dodson** principio que establece que el rendimiento aumenta con la excitación solamente hasta un punto; más allá de este punto el rendimiento disminuye. (p. 404)
Young-Helmholtz trichromatic (three-color) theory the theory that the retina contains three different types of color receptors—one most sensitive to red, one to green, one to blue—which, when stimulated in combination, can produce the perception of any color. (p. 181)	**teoría tricromática de Young-Helmholtz** teoría de que la retina contiene tres tipos distintos de receptores de color: uno más sensible al rojo, otro al verde y otro al azul. Al estimularse en conjunto, estos receptores son capaces de producir la percepción de cualquier color. (p. 181)
Z	
zygote the fertilized egg; it enters a 2-week period of rapid cell division and develops into an embryo. (p. 489)	**cigoto** huevo fertilizado. Atraviesa por un período de dos semanas de división celular rápida y se convierte en un embrión. (p. 489)

Subject Index

A

Absolute threshold, 162–163

Abuse

- dissociative disorders and, 709–710
- false/repressed memories of, 355, 360–361, 745
- long-term effects of, 514–515
- modeling of aggression and, 804

Acceptance, 592

Accidents

- human factors psychology and, 845
- selective attention and, 159–160
- sleep deprivation and, 241, 243

Accommodation

- cognitive, 498–499
- visual, 177

Acetylcholine (ACh), 87

Achievement

- distributed vs. massed practice and, 21, 334–335
- online time and, 427–428
- ten-year rule for, 629

Achievement motivation, 428–430, 840–844

Achievement tests, 633. *See also* Test(s)

- predictive validity of, 637

Acquired immunodeficiency syndrome (AIDS)

  stress and, 457
  transmission of, 547–548
Acquisition, in classical conditioning, 275–276, 297
Acronyms, 334
Action potential, 83–84
Activation-synthesis theory, 249
Active listening, 726
Acupuncture, 208, 209
Adaptation. *See also* Evolution
  classical conditioning and, 272, 275, 301–302
  happiness and, 475–476
  intuition and, 377, 378
  natural selection and, 8, 14, 141–142
  nature–nurture issue and, 14
  perceptual, 195
  sensory, 165–166
Adaptation-level phenomenon, 476
Addiction, 106, 253, 254, 263. *See also* Alcohol use disorder; Psychoactive drugs
Adolescence, definition of, 533
Adolescents
  bipolar disorder in, 688
  brain development in, 534–535
  cognitive development in, 535–537
  emerging adulthood and, 542–543
  hearing loss in, 200–201
  identity formation in, 539–541
  impulsivity in, 534
  moral development in, 535–537
  parental influence on, 541–542
  peer relationships of, 541–542, 830, 831
  physical development in, 533–535
  pregnant, 548–549
  preventive mental health programs for, 760

- reasoning power in, 535
- sexual development in, 533–534, 543, 545–547
- social development in, 543

Adoption studies, 134–135
- of intelligence, 648–649
- of schizophrenia, 703
- on substance use, 830

Adrenal glands, 96

Adrenaline, 95

Adulthood. *See also* Aging
- cognitive development in, 561–564
- emerging, 542–543
- life satisfaction in, 472–478
- love in, 565–566
- midlife transition in, 564
- milestones in, 543
- physical development in, 558–561
- psychosocial development in, 540
- social development in, 564–567
- stages of, 558, 564–565
- work in, 567

Aerobic exercise, 752. *See also* Exercise

Affect, in schizophrenia, 700

Affiliation needs, 423–428

Afterimages, opponent-process theory and, 181–182

Aggression, 801–806. *See also* Violence
- alcohol and, 802–803
- amygdala and, 104
- anger and, 460
- aversive events and, 803
- biochemical influences in, 802–803
- biology of, 801–803
- biopsychosocial approach to, 806

  - cultural factors in, 804
  - definition of, 801
  - frustration and, 803
  - gender differences in, 521
  - genetic factors in, 801
  - modeling of, 312–313, 316–318, 804–805
  - neural influences in, 801–802
  - psychological factors in, 803–806
  - punishment and, 290
  - reinforcement of, 804
  - relational, 521 (*See also* Ostracism)
  - social-cultural factors in, 803–806
  - social isolation and, 426
  - social scripts and, 804–805
  - testosterone and, 802
  - threatened egotism and, 615
- Aging. *See also* Adulthood
  - biopsychosocial approach to, 568
  - cognitive changes and, 561–564, 640–642
  - intelligence and, 640–642
  - life satisfaction and, 567–568
  - physical changes and, 559–561
  - stress and, 455
  - successful, 568
- Agonists, neurotransmitters and, 88
- Agoraphobia, 678
- Agreeableness, 599, 600
- AIDS
  - stress and, 457
  - transmission of, 547–548
- Alcoholics Anonymous, 738
- Alcohol use, 255–257, 263
  - aggression and, 802–803

- disinhibition and, 255, 256, 257
- expectancy effects and, 256–257
- fetal effects of, 490
- neural processing and, 256
- reward centers and, 106
- self-awareness and self-control and, 256
- sexual behavior and, 255, 548
- trends in, 829

Alcohol use disorder, 256

- aversive therapy for, 731–732
- biological influences in, 829–830
- genetic factors in, 830
- suicide and, 695

Algorithms, 370
All-or-none response, 83
Alpha waves, during sleep, 232–233
Alternative therapies, 745–746

- eye movement desensitization and reprocessing therapy, 745–746
- light exposure therapy, 746

Altruism, 816–819

- bystander effect and, 816–818
- definition of, 816
- happiness and, 818
- reciprocity norm and, 818–819
- social exchange theory and, 818
- social responsibility norm and, 819

Alzheimer’s disease, 326, 343, 563–564
American Psychological Association (APA), ethical guidelines of, 61, 62
Amnesia. *See also* Forgetting; Memory loss

- anterograde, 351
- brain lesions and, 341
- infantile, 341, 360, 495

- retrograde, 351
- source, 358–359

Amok, 668

Amphetamines, 257, 261, 263

Amygdala, 104

- age-related changes in, 568
- emotions and, 435
- in memory, 341–342

Anal stage, 580–581

Analytical intelligence, 628

Ancient Greece, 6, 14

Androgyny, 526

Anger, 460–461

- gender differences in, 444
- health effects of, 459–461

Animal(s)

- breeding of, 141–142
- cognition in, 848–850
- communication in, 849–850
- same-sex attraction in, 552
- tool use by, 848
- use in research, 61–62, 301

Anorexia nervosa, 712–714

- biopsychosocial approach on, 668

Anosmia, 211

Antagonists, neurotransmitters and, 89

Anterior cingulate cortex

- in anxiety disorders, 683
- ostracism and, 425

Anterograde amnesia, 351

Antianxiety drugs, 754

Antidepressants, 692, 753–754

Antipsychotics, 753–754
Antisocial personality disorder, 710–712
Anvil (ear), 199, 200
Anxiety
  adaptive function of, 684
  defense mechanisms and, 581–582, 586–587
  free-floating, 678
  online time and, 427–428
  psychoanalytic view of, 581–582, 586–587, 588
  psychodynamic view of, 583
  stranger, 509
Anxiety disorders, 677–684
  aversive conditioning for, 731
  biological perspective on, 683–684
  brain activity in, 683
  classification of, 677
  cognitive-behavioral therapy for, 736–737
  drug therapy for, 754
  exposure therapy for, 730
  generalized anxiety disorder, 677–678
  genetic factors in, 684
  learning perspective on, 681–682
  natural selection and, 684
  panic disorder, 677
  phobias, 677, 679
Aphasia, 387–388
  Broca's, 388
  Wernicke's, 388
Aplysia, 342
Apnea, sleep, 245–246, 248
Appetite, hunger. *See also* Eating
  regulation of, 243, 409–411

Applied research, 24
  careers in, 24–25, 28–30
  ethics in, 59–63
Aptitude tests, 633, Test(s). *See also* Intelligence tests
  bias and, 656–658
  predictive validity of, 637, 657
  stability of scores in, 642–643
  stereotype threat and, 657
Archetypes, 583
Arcuate nucleus, hunger and, 410
Arousal, 432–436
  autonomic nervous system in, 437–438, 598
  motivation and, 403–404
  passionate love and, 812–813
  personality and, 596, 598

Footnotes

Module 1

[1] If you are a student using these Multiple-Choice Questions for self-testing, please consult with your teacher to check your answers.

Module 2

[1] Confession: I [DM] wrote the last part of this sentence on April Fool's Day.

[2] Also sometimes called "*R*ecite."

Module 4

[1] Boston is south of Paris.

[2] The anagram solution: CHAOS

Module 5

[1] These researchers were able to carefully observe and record naturally occurring behaviors outside the artificiality of a laboratory. However, outside the lab they were not able to control for all the factors that may have influenced the everyday interactions they were recording.

Module 6

[1] negative

[2] positive

[3] positive

[4] negative

[5] In this case, as in many others, a third factor can explain the correlation: Golden anniversaries and baldness both accompany aging.

[6] The *independent variable,* which the researchers manipulated, was the ethnicity-related names. The *dependent variable,* which they measured, was the positive response rate.

Module 9

[1] ANSWER: Morphine is an agonist; curare is an antagonist.

Module 11

[1] Answer: The cat would be aroused via its sympathetic nervous system.

Module 13

[1] So, would the reverse damage lead to the opposite symptoms? Indeed, there are a few such patients—who can see and recognize objects but have difficulty pointing toward or grasping them.

Module 17

[1] The title's first error is its repeated "The." Its ironic second error is its misstatement that there are two errors, when there is only one.

Module 18

[1] Answer: Your blind spot is on the nose side of each retina, which means that objects to your right may fall onto the right eye's blind spot. Objects to your left may fall on the left eye's blind spot. The blind spot does not normally impair your vision, because your eyes are moving and because one eye catches what the other misses. Moreover, even with only one eye open, our brain gives us a perception without a hole in it.

Module 25

[1] This analogy, adapted here with world-based numbers, was suggested by mathematician Sam Saunders, as reported by K. C. Cole (1998).

Module 26

[1] The “buzzer” (English translation) was perhaps the bell people commonly associate with Pavlov (Tully, 2003). Pavlov used various stimuli, but some have questioned whether he used a bell.

[2] ANSWER: generalization

[3] ANSWER: The US was the loud noise; the UR was the fear response to the noise; the NS was the rat before it was paired with the noise; the CS was the rat after pairing; the CR was fear of the rat.

Module 27

[1] ANSWER: The baby negatively reinforces her parents’ behavior when she stops crying once they grant her wish. Her parents positively reinforce her cries by letting her sleep with them.

Module 33

[1] One of my cookie-scarfing sons, on reading this in his father’s textbook years later, confessed he had fibbed “a little.”

[2] bicycle, void, cigarette, inherent, fire, process

Module 35

[1] Answer to SPLOYOCHYG anagram: PSYCHOLOGY.

[2] The word is *apple:* pineapple, crabapple, applesauce.

[3] The first answer is 5 cents. The bat would then cost $1.05, for a $1.10 total. If the ball cost the intuitive answer of 10 cents, the bat would then have to cost $1.10 (for a bat-and-ball total of $1.20, not $1.10). The second answer is 5 minutes, because each machine makes a widget every 5 minutes. If you answered incorrectly, don’t feel bad—so do most university students (Frederick, 2005).

Module 36

[1] How did you illustrate “the girl pushes the boy”? Anne Maass and Aurore Russo (2003) report that people whose language reads from left to right mostly position the pushing girl on the left. Those who read and write Arabic, a right-to-left language, mostly place her on the right. This spatial bias appears only in those old enough to have learned their culture’s writing system (Dobel et al., 2007).

Module 40

[1] Note: The researchers later *debriefed* and reassured the participants.

Module 42

[1] From left to right, top to bottom: happiness, surprise, fear, sadness, anger, disgust.

[2] ANSWERS: (1) Most students report feeling more happy than sad when their cheeks are raised upward. (2) Most students report feeling more sad than happy when their cheeks are pulled downward.

Module 45

[1] By one careful estimate, the average human has 37.2 trillion cells (Bianconi et al., 2013).

Module 53

[1] Answer: Figure (c)

Module 59

[1] We couldn’t resist throwing that in. But don’t worry, you won’t be tested on floccinaucinihilipilification, which is the act of estimating something as worthless (and was the longest nontechnical word in the first edition of the *Oxford English Dictionary*).

Module 64

[1] ANSWER: The correct answer is c.

Module 65

[1] A book of case illustrations accompanying the previous DSM edition provided several examples for this unit.

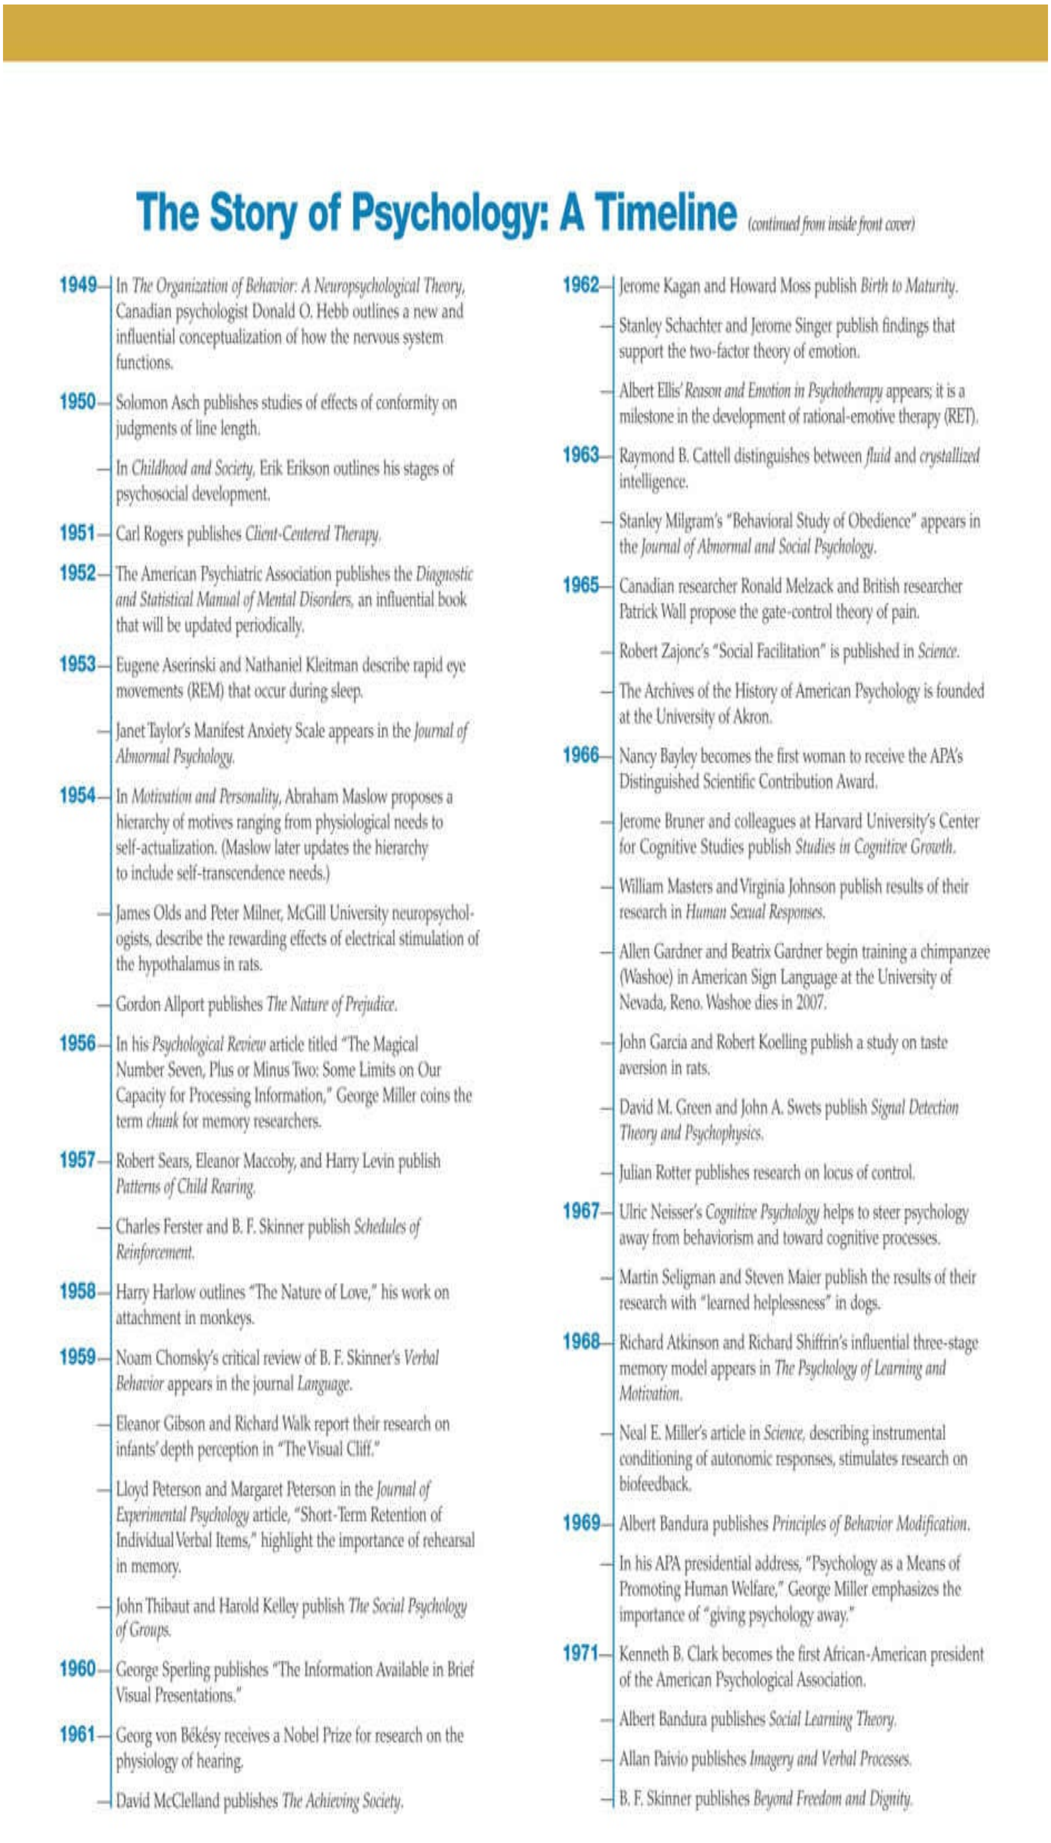
Module 66

[1] OCD and PTSD were formerly classified as anxiety disorders, but the DSM-5 now classifies them separately.

[2] Because the behaviors result in removal or reduction of unpleasant anxiety, they are examples of *negative reinforcement*.

Appendix D

[1] Although this appendix draws primarily from available U.S. data, its descriptions of psychology’s subfields and suggestions for preparing for further psychology studies are applicable to students in many other countries.



The Story of Psychology: A Timeline *(continued from inside front cover)*

- **1949** In *The Organization of Behavior: A Neuropsychological Theory,* Canadian psychologist Donald O. Hebb outlines a new and influential conceptualization of how the nervous system functions.
- **1950** Solomon Asch publishes studies of effects of conformity on judgments of line length.
- In *Childhood and Society,* Erik Erikson outlines his stages of psychosocial development.
- **1951** Carl Rogers publishes *Client-Centered Therapy.*
- **1952** The American Psychiatric Association publishes the *Diagnostic and Statistical Manual of Mental Disorders,* an influential book that will be updated periodically.
- **1953** Eugene Aserinski and Nathaniel Kleitman describe rapid eye movements (REM) that occur during sleep.
- Janet Taylor's Manifest Anxiety Scale appears in the *Journal of Abnormal Psychology.*
- **1954** In *Motivation and Personality,* Abraham Maslow proposes a hierarchy of motives ranging from physiological needs to self-actualization. (Maslow later updates the hierarchy to include self-transcendence needs.)
- James Olds and Peter Milner, McGill University neuropsychologists, describe the rewarding effects of electrical stimulation of the hypothalamus in rats.
- Gordon Allport publishes *The Nature of Prejudice.*
- **1956** In his *Psychological Review* article titled "The Magical Number Seven, Plus or Minus Two: Some Limits on Our Capacity for Processing Information," George Miller coins the term *chunk* for memory researchers.
- **1957** Robert Sears, Eleanor Maccoby, and Harry Levin publish *Patterns of Child Rearing.*
- Charles Ferster and B. F. Skinner publish *Schedules of Reinforcement.*
- **1958** Harry Harlow outlines "The Nature of Love," his work on attachment in monkeys.
- **1959** Noam Chomsky's critical review of B. F. Skinner's *Verbal Behavior* appears in the journal *Language.*
- Eleanor Gibson and Richard Walk report their research on infants' depth perception in "The Visual Cliff."
- Lloyd Peterson and Margaret Peterson in the *Journal of Experimental Psychology* article, "Short-Term Retention of Individual Verbal Items," highlight the importance of rehearsal in memory.
- John Thibaut and Harold Kelley publish *The Social Psychology of Groups.*
- **1960** George Sperling publishes "The Information Available in Brief Visual Presentations."
- **1961** Georg von Békésy receives a Nobel Prize for research on the physiology of hearing.
- David McClelland publishes *The Achieving Society.*
- **1962** Jerome Kagan and Howard Moss publish *Birth to Maturity.*
- Stanley Schachter and Jerome Singer publish findings that support the two-factor theory of emotion.
- Albert Ellis' *Reason and Emotion in Psychotherapy* appears; it is a milestone in the development of rational-emotive therapy (RET).
- **1963** Raymond B. Cattell distinguishes between *fluid* and *crystallized* intelligence.
- Stanley Milgram's "Behavioral Study of Obedience" appears in the *Journal of Abnormal and Social Psychology.*
- **1965** Canadian researcher Ronald Melzack and British researcher Patrick Wall propose the gate-control theory of pain.
- Robert Zajonc's "Social Facilitation" is published in *Science.*
- The Archives of the History of American Psychology is founded at the University of Akron.
- **1966** Nancy Bayley becomes the first woman to receive the APA's Distinguished Scientific Contribution Award.
- Jerome Bruner and colleagues at Harvard University's Center for Cognitive Studies publish *Studies in Cognitive Growth.*
- William Masters and Virginia Johnson publish results of their research in *Human Sexual Responses.*
- Allen Gardner and Beatrix Gardner begin training a chimpanzee (Washoe) in American Sign Language at the University of Nevada, Reno. Washoe dies in 2007.
- John Garcia and Robert Koelling publish a study on taste aversion in rats.
- David M. Green and John A. Swets publish *Signal Detection Theory and Psychophysics.*
- Julian Rotter publishes research on locus of control.
- **1967** Ulric Neisser's *Cognitive Psychology* helps to steer psychology away from behaviorism and toward cognitive processes.
- Martin Seligman and Steven Maier publish the results of their research with "learned helplessness" in dogs.
- **1968** Richard Atkinson and Richard Shiffrin's influential three-stage memory model appears in *The Psychology of Learning and Motivation.*
- Neal E. Miller's article in *Science,* describing instrumental conditioning of autonomic responses, stimulates research on biofeedback.
- **1969** Albert Bandura publishes *Principles of Behavior Modification.*
- In his APA presidential address, "Psychology as a Means of Promoting Human Welfare," George Miller emphasizes the importance of "giving psychology away."
- **1971** Kenneth B. Clark becomes the first African-American president of the American Psychological Association.
- Albert Bandura publishes *Social Learning Theory.*
- Allan Paivio publishes *Imagery and Verbal Processes.*
- B. F. Skinner publishes *Beyond Freedom and Dignity.*

1972
- Elliot Aronson publishes *The Social Animal.*
- Fergus Craik and Robert Lockhart's "Levels of Processing: A Framework for Memory Research" appears in the *Journal of Verbal Learning and Verbal Behavior.*
- Robert Rescorla and Allan Wagner publish their associative model of Pavlovian conditioning.
- Under the leadership of Derald Sue and Stanley Sue, the Asian American Psychological Association is founded.

1973
- Ethologists Karl von Frisch, Konrad Lorenz, and Nikolaas Tinbergen receive the Nobel Prize for their research on animal behavior.

1974
- APA's Division 2 first publishes its journal, *Teaching of Psychology,* with Robert S. Daniel as editor.
- Eleanor Maccoby and Carol Jacklin publish *The Psychology of Sex Differences.*

1975
- Biologist Edward O. Wilson's *Sociobiology* appears; it will be a controversial precursor to evolutionary psychology.

1976
- Sandra Wood Scarr and Richard A. Weinberg publish "IQ Test Performance of Black Children Adopted by White Families" in *American Psychologist.*
- Psychologist Robert V. Guthrie publishes *Even the Rat Was White,* the first history of African-American psychologists in America.

1978
- Psychologist Herbert A. Simon, Carnegie-Mellon University, wins a Nobel Prize for pioneering research on computer simulations of human thinking and problem solving.

1979
- James J. Gibson publishes *The Ecological Approach to Visual Perception.*
- Elizabeth Loftus publishes *Eyewitness Testimony.*

1981
- David Hubel and Torsten Wiesel receive a Nobel Prize for research on single-cell recordings that identified feature detector cells in the visual cortex.
- Roger Sperry receives a Nobel Prize for research on split-brain patients.
- Paleontologist Stephen Jay Gould publishes *The Mismeasure of Man,* highlighting the debate concerning biological determination of intelligence.

1983
- In his *Frames of Mind,* Howard Gardner outlines his theory of multiple intelligences.

1984
- The American Psychological Association creates Division 44 (Society for the Psychological Study of Lesbian and Gay Issues).
- Robert Sternberg proposes the triarchic theory of human intelligence in *Behavioral and Brain Sciences.*

1987
- Elizabeth Scarborough and Laurel Furumoto publish *Untold Lives: The First Generation of American Women Psychologists.*
- Fluoxetine (Prozac) is introduced as a treatment for depression.
- Wilbert J. McKeachie, University of Michigan, receives the first APA Award for Distinguished Career Contributions to Education and Training in Psychology.

1988
- The American Psychological Society is founded. It changes its name to Association for Psychological Science in 2006.

1990
- Psychiatrist Aaron Beck receives the Distinguished Scientific Award for the Applications of Psychology for advancing understanding and treatment of psychopathology, including pivotal contributions to the development of cognitive therapy.
- B. F. Skinner receives APA's first Citation for Outstanding Lifetime Contributions to Psychology and presents his last public address, "Can Psychology Be a Science of Mind?" (He died a few days later at age 86.)

1991
- Martin Seligman publishes *Learned Optimism,* which foreshadows the "positive psychology" movement.

1992
- Teachers of Psychology in Secondary Schools (TOPSS) is established as part of the APA.
- About 3,000 U.S. secondary school students take the first Advanced Placement (AP) Examination in Psychology, hoping to earn exemption from an introductory psychology course at the postsecondary level.

1993
- Psychologist Judith Rodin is elected president of the University of Pennsylvania, becoming the first female president of an Ivy League school.

1996
- Dorothy Cantor becomes the first president of the APA with a Psy.D. degree.

2002
- New Mexico becomes the first U.S. state to allow qualified clinical psychologists to prescribe certain drugs.
- Psychologist Daniel Kahneman, Princeton University, receives a Nobel Prize for research on decision making.

2011
- Proposed by participants at the 2008 national conference at the University of Puget Sound, the document, "Principles for Quality Undergraduate Education in Psychology," is approved as official APA policy.

2013
- U.S. President Barack Obama announces $100 million in funding for an interdisciplinary project to advance understanding of the human brain.

2015
- The *Independent Review Relating to APA Ethics Guidelines, National Security Interrogations, and Torture* is presented to the American Psychological Association.

Gear Up for AP® Psychology

Welcome to AP® psychology, where you will learn more about yourself, your teachers, your family and friends, and even your pets, all while preparing for the AP® exam.

This book has an abundance of AP® tools to help you succeed:

- The **coverage** matches perfectly with the requirements for the AP® psychology course.
- **AP® Exam Tips** direct your attention to important concepts to know for the exam.
- Module- and Unit-ending **AP® Practice Questions** assess your understanding throughout the year.
- Lists of psychology's **Key Terms and Concepts** and **Key Contributors** help you to remember important names and theories.
- A full-length **Practice AP®-Style Exam** allows you to put your knowledge to the test.
- The **Strive for a 5** supplement supports your learning throughout the year and includes two additional full-length practice exams.

But you won't just use this book—you will love it. How do we know? Students just like you regularly contact the authors with feedback and appreciation for producing a text that is both enlightening and engaging.

> "Thank you so much for making psychology even more captivating than it already is and for keeping me engrossed throughout [the] entire 80 modules of your book. With your guidance, I received a 5 on the AP® test and I'm extremely grateful for that."
>
> —Kurt Klaus, Westmont High School

> "I would just like to say thank you for creating this book. Although this was the hardest class I have ever taken in my life, I feel like this book truly helped me prepare for my AP® test.... I have taken so much away from this class and I will never forget this experience."
>
> —Lela Jimenez, Woodhaven High School

> "...your command of language, the occasional witty remarks and puns, the frequent inclusion of concrete psychological experiments pertaining to the respective subject.... I often found myself nodding my head while reading along, as I felt like the information I was taking in was substantiated with real-life applications."
>
> —Sabrina Halavi, Beverly Hills High School

> "A textbook can make or break a class for me, and yours was a constant, invaluable resource to my learning about psychology. Without it, I am not quite sure I would have gotten a 5 on the AP® exam!"
>
> —Marcel Werder, Harriton High School

Open the pages to find your favorite topics and stories. We guarantee that this will be a book you'll remember far beyond the AP® exam.

A NOTE TO TEACHERS This book was crafted to address the requirements of the AP® psychology course, and we offer unmatched support. To learn more about our teacher resources, including the new Teacher's Edition from AP® expert Elizabeth Yost Hammer, please contact your local BFW sales representative or visit **highschool.bfwpub.com/myersap3e**.

Enrichment Modules 61

Unit I Psychology’s History and Approaches 63

Module 1 Psychology and Its History 65

Psychology Is a Science 67

Thinking Critically About: The Scientific Attitude 69

Critical Thinking 71

Prescientific Psychology 76

Psychological Science Is Born 79

Psychological Science Matures 86

Module 1 Review 90

Module 2 Today’s Psychology and Its Approaches 95

Contemporary Psychology 96

The Biopsychosocial Approach and Psychology’s Theoretical Perspectives 105

Use Psychology to Become a Stronger Person—and a Better Student 112
Module 2 Review 118
Module 3 Subfields in Psychology 122
Basic and Applied Psychology 124
Psychology’s Main Subfields 129
Module 3 Review 140
Unit I Review 144
Unit II Research Methods: Thinking Critically With Psychological Science 152
Module 4 The Need for Psychological Science 154
Did We Know It All Along? Hindsight Bias 156
Overconfidence 158
Perceiving Order in Random Events 160
Module 4 Review 162
Module 5 The Scientific Method and Description 165
The Scientific Method 166
Description 171
Module 5 Review 181
Module 6 Correlation and Experimentation 185
Correlation 186
Thinking Critically About: Correlation and Causation 191
Experimentation 195
Module 6 Review 205
Module 7 Research Design and Ethics in Psychology 210
Research Design 211
Understanding Everyday Behavior 214
Psychology’s Research Ethics 216
Module 7 Review 223
Module 8 Statistical Reasoning in Everyday Life 227
The Need for Statistics 228
Descriptive Statistics 230
Inferential Statistics 238
Module 8 Review 243
Unit II Review 248

Unit III Biological Bases of Behavior 258
Module 9 Biological Psychology and Neurotransmission 261
Biology, Behavior, and Mind 262
Neural Communication 266
Module 9 Review 284
Module 10 The Nervous and Endocrine Systems 289
The Nervous System 290
The Endocrine System 299
Module 10 Review 303
Module 11 Studying the Brain, Older Brain Structures, and the Limbic System 307
The Tools of Discovery: Having Our Head Examined 309
Older Brain Structures 319
The Limbic System 325
Module 11 Review 333
Module 12 The Cerebral Cortex 337
Structure of the Cortex 339
Functions of the Cortex 341
Thinking Critically About: Using More Than 10 Percent of Our Brain 350
The Power of Plasticity 354
Module 12 Review 360
Module 13 Brain Hemisphere Organization and the Biology of Consciousness 364
The Divided Brain 365
The Biology of Consciousness 374
Module 13 Review 383
Module 14 Behavior Genetics: Predicting Individual Differences 387
Genes: Our Codes for Life 389
Twin and Adoption Studies 394
Heritability 405
Gene-Environment Interaction 408
Module 14 Review 414
Module 15 Evolutionary Psychology: Understanding Human Nature 418

Natural Selection and Adaptation 420
Evolutionary Success Helps Explain Similarities 422
An Evolutionary Explanation of Human Sexuality 425
Reflections on Nature, Nurture, and Their Interaction 433
Module 15 Review 440
Unit III Review 443
Unit IV Sensation and Perception 455
Module 16 Basic Concepts of Sensation and Perception 458
Processing Sensation and Perception 459
Selective Attention 462
Transduction 470
Thresholds 471
Thinking Critically About: Subliminal Sensation and Subliminal Persuasion 475
Sensory Adaptation 477
Module 16 Review 481
Module 17 Influences on Perception 485
Perceptual Set 486
ESP—Perception Without Sensation? 496
Module 17 Review 503
Module 18 Vision: Sensory and Perceptual Processing 506
Light Energy and Eye Structures 507
Information Processing in the Eye and Brain 513
Module 18 Review 530
Module 19 Visual Organization and Interpretation 534
Perceptual Organization 535
Perceptual Interpretation 553
Module 19 Review 558
Module 20 Hearing 563
The Stimulus Input: Sound Waves 565
The Ear 568
Perceiving Loudness, Pitch, and Location 574
Module 20 Review 579
Module 21 The Other Senses 583
Touch 584

Pain 586
Taste 596
Smell 599
Body Position and Movement 604
Sensory Interaction 607
Module 21 Review 613
Unit IV Review 617
Unit V States of Consciousness 627
Module 22 Understanding Consciousness and Hypnosis 629
Defining Consciousness 630
Hypnosis 632
Module 22 Review 641
Module 23 Sleep Patterns and Sleep Theories 644
Biological Rhythms and Sleep 646
Why Do We Sleep? 660
Module 23 Review 664
Module 24 Sleep Deprivation, Sleep Disorders, and Dreams 668
Sleep Deprivation and Sleep Disorders 669
Dreams 684
Module 24 Review 695
Module 25 Psychoactive Drugs 699
Tolerance and Addiction in Substance Use Disorders 700
Thinking Critically About: Tolerance and Addiction 702
Types of Psychoactive Drugs 704
Module 25 Review 726
Unit V Review 731
Unit VI Learning 738
Module 26 How We Learn and Classical Conditioning 741
How Do We Learn? 742
Classical Conditioning 749
Module 26 Review 768
Module 27 Operant Conditioning 773
Skinner’s Experiments 775
Skinner’s Legacy 795
Module 27 Review 797

Module 28 Operant Conditioning’s Applications, and Comparison to Classical Conditioning 802
    Applications of Operant Conditioning 803
    Contrasting Classical and Operant Conditioning 810
    Module 28 Review 812
Module 29 Biology, Cognition, and Learning 815
    Biological Constraints on Conditioning 817
    Cognition’s Influence on Conditioning 825
    Learning and Personal Control 833
    Module 29 Review 842
Module 30 Observational Learning 846
    Mirrors and Imitation in the Brain 850
    Applications of Observational Learning 855
    Thinking Critically About: The Effects of Viewing Media Violence 859
    Module 30 Review 861
Unit VI Review 865
Unit VII Cognition 876
Module 31 Studying and Encoding Memories 878
    Studying Memory 880
    Encoding Memories 892
    Module 31 Review 909
Module 32 Storing and Retrieving Memories 914
    Memory Storage 915
    Memory Retrieval 929
    Module 32 Review 937
Module 33 Forgetting, Memory Construction, and Improving Memory 942
    Forgetting 943
    Memory Construction Errors 959
    Thinking Critically About: Can Memories of Childhood Sexual Abuse Be Repressed and Then Recovered? 968
    Improving Memory 972
    Module 33 Review 975
Module 34 Thinking, Concepts, and Creativity 980

Concepts 981
Thinking Creatively 984
Module 34 Review 990
Module 35 Solving Problems and Making Decisions 993
Problem Solving: Strategies and Obstacles 994
Forming Good (and Bad) Decisions and Judgments 1001
Thinking Critically About: The Fear Factor 1007
Module 35 Review 1020
Module 36 Thinking and Language 1024
Language Structure 1027
Language Acquisition and Development 1030
The Brain and Language 1043
Language and Thought 1048
Module 36 Review 1058
Unit VII Review 1062
Unit VIII Motivation, Emotion, and Stress 1075
Module 37 Motivational Concepts 1078
Instinct Theory 1080
Drives and Incentives 1082
Arousal Theory 1085
A Hierarchy of Needs 1088
Module 37 Review 1093
Module 38 Hunger Motivation 1096
The Physiology of Hunger 1099
The Psychology of Hunger 1105
Thinking Critically About: The Challenges of Obesity and Weight Control 1111
Module 38 Review 1113
Module 39 Sexual Motivation 1117
The Physiology of Sex 1118
The Psychology of Sex 1124
Module 39 Review 1128
Module 40 Affiliation and Achievement 1131
The Need to Belong 1132
Achievement Motivation 1147

- Module 40 Review 1152
- Module 41 Theories and Physiology of Emotion 1155
  - Emotion: Arousal, Behavior, and Cognition 1158
  - Embodied Emotion 1169
  - Thinking Critically About: Lie Detection 1174
  - Module 41 Review 1176
- Module 42 Expressing Emotion 1180
  - Detecting Emotion in Others 1181
  - Gender, Emotion, and Nonverbal Behavior 1185
  - Culture and Emotional Expression 1188
  - The Effects of Facial Expressions 1193
  - Module 42 Review 1197
- Module 43 Stress and Illness 1200
  - Stress: Some Basic Concepts 1202
  - Thinking Critically About: Stress and Health 1226
  - Module 43 Review 1228
- Module 44 Health and Happiness 1232
  - Promoting Health 1233
  - Reducing Stress 1240
  - Happiness 1253
  - Module 44 Review 1268
- Unit VIII Review 1273

Unit IX Developmental Psychology 1283

- Module 45 Developmental Issues, Prenatal Development, and the Newborn 1286
  - Developmental Psychology’s Major Issues 1287
  - Prenatal Development and the Newborn 1294
  - Module 45 Review 1304
- Module 46 Infancy and Childhood: Physical Development 1308
  - Brain Development 1309
  - Motor Development 1311
  - Brain Maturation and Infant Memory 1313
  - Module 46 Review 1316
- Module 47 Infancy and Childhood: Cognitive Development 1319
  - Piaget’s Theory and Current Thinking 1323

- An Alternative Viewpoint: Lev Vygotsky and the Social Child 1334
- Reflecting on Piaget’s Theory 1337
- Autism Spectrum Disorder 1339
- Module 47 Review 1345

Module 48 Infancy and Childhood: Social Development 1350
- Origins of Attachment 1352
- Attachment Differences: Temperament and Parenting 1356
